VOLUME XXXIX
Number 1.

Earthquakes.—No. 2.

This most conspicuous example of a vorticosc earthquake, in which the ground is twisted and whirled around and back, occurred in the great Calabrian earthquake of 1783. Blocks of stones forming obelisks were twisted one on another; the earth was broken and twisted, so that straight rows of trees were left in interrupted zigzags. Similar phenomena were observed in the California earthquake of 1868. Chimney-tops were separated at their junction with the roof, and twisted around without overthrow; wardrobes and bureaus were turned about at right angles to the wall, or even with their faces to the wall. These phenomena may be explained by the backward and forward motion common to all earthquakes—the sudden lifting up of one end by a forward motion, would swing around by the sudden backward motion. The concurrence and interferences of earth-waves would produce the real vorticosc motion. If two systems of waves of any kind meet each other, there will be points of concurrence where they re-enforce each other, and points of interference where they destroy each other. Suppose, for example, a system of water waves, represented by the double lines, *i, i*, (Fig. 1), moving in the direction *b, b*, strike against a wall, *w, w*; the waves would be reflected in the direction *c, c*, and are represented by the single lines, *r, r*. Then, if the lines represent crests, and the intervening spaces the troughs, at the place marked with crosses and dots there would be concurrence, and, therefore, higher crests and deeper troughs, while at the points indicated by dashes there would be interference and mutual destruction, and, therefore, smooth water. When two systems of earth-waves meet and interfere, we must have points of concurrence and interference in close proximity. The ground, therefore, will be thrown into violent vibration—points in close proximity moving in opposite directions (twisting). If the motion is sufficient to rupture the earth, restoration is made by counter-twisting, and the earth is left in a displaced condition. The cause of this interference lies in the different velocity of waves—as has been explained, an inequality in the medium. It is a noticeable fact that the most violent earthquakes, especially twisting of the ground, occur near the junction of the softer strata of the plains with the harder and more elastic strata of the mountains, as will appear from Fig. 2. From the point of the shock, *X*, suppose earth-waves to emerge at *a*, and run as a surface-wave toward the mountain, *m*. The waves, striking the hard, elastic material, *m*, would be partly transmitted and partly reflected. The reflected waves, running in the direction of the arrow, *r*, would meet the advancing incident waves moving in the direction of the arrow, *i*, and concurrence and interference would be inevitable. The hollow mumbled, rolling or grinding preceding and accompanying an earthquake are produced by the rupture of the earth at the origin, and by the passage of the wave through the variable elastic medium, being the sound produced by the breaking of the medium and the grinding of the broken parts together. Waves of every variety of size are transmitted, the great waves being sensible as shocks, jars or tremors, while the small waves which do not produce tremors are heard as sounds. The smaller waves running faster than the large ones, are heard first, and thus precede the shock.

Whether the direction of the earthquake be up and down, back and forth, or oblique, the observed motion is due to the position of the observer. At the outcrop the motion would be up and down, becoming oblique the further the observer recedes from the epicentrum, until at a great distance the motion is usually horizontal. The rocking motion is due to a series of waves which pass beneath the observer, waves similar in form to water waves.

It has been observed that in a certain zone, a considerable distance from the epicentrum, the destruction by overthrow is very great, and beyond it the effects speedily diminish. This zone has been called the circle of principal destruction or overflow. This depends not so much on the amount of oscillation as upon the horizontal nature of the oscillation. The oscillation or vibration is of course greatest at this point of first emergence, the epicentrum, and decreases outward. The oscillation increasing at the epicentrum and decreasing beyond that. Under the influence of these two contrary elements, there must exist a point or circle on every side of the epicentrum when the horizontal element will be a maximum. This is shown in Fig. 3, in which *a, a*, *b, b*, *c, c*, etc., are the decreasing oscillation, and *b, b*, *c, c*, etc., are the horizontal element. This reaches a maximum at *c*. It has been found by mathematical calculation, based upon the supposition that the whole oscillation varies inversely as the square of the distance from *X*, that the horizontal element will be a maximum when the angle of emergence is $54^{\circ} 44'$. By determining by observation the circle of principal disturbance, it is easy to calculate the depth, *a, X*, of the forces, for it will be the apex of a cone whose base is that circle and whose apical angle is $70^{\circ} 32'$. It has been noticed that shocks are sometimes

waves, and producing great commotion in these strata. Now, if the inelastic strata *S, S*, be located at the bottom of a mine, the same effect would be apparent, viz., the undulations would be reflected at the bottom of the strata, to reappear at the surface of the ground above the strata.

In the earthquake regions of South America there are certain favored spots, often of small extent, which are partially exempt from the shocks which infect the surrounding country. The wave seems to pass under them as under a bridge to reappear again on the other side. An inspection of Fig. 5 will explain the cause to be reflection from an under surface of inelastic strata. According to Mallet, the geological structure of the earth, the formations at the surface and below the surface, have nearly everything to do with the violence of the earthquake. Two cities may be near together, yet one would be totally destroyed by the shock, and the other entirely escape, or different houses may escape or suffer according to the strata upon which they rest. Immunity from earthquakes may be had, few, if any, human lives need ever be lost by earthquakes even in volcanic countries. There, earthquakes recur in their "times and seasons," and to be dealt with, like all human difficulties, they must be understood. The informed faculties and energies of

distinctly felt in mines which are insensible at the surface, and again are felt at the surface and not felt in the mine. This latter has lately happened in our own mines, and may be explained in both cases by the elasticity of the strata, the depth of the impulses or obstacles that may have changed the course of the terrestrial undulations. In Fig. 4, *S, S*, represents the surface of the ground; *a, b*, hard, elastic strata, covered with loose, inelastic materials; *c, c*, earth, gravel, etc. Now, if a series of waves come in the direction of the arrow, *d, d*, and, passing through *a, b*, on their way to the surface, strike upon the lower surface of *c, c*, a portion would reach the surface by refraction, but a greater portion would be reflected and return into *a, b*, concurring and interfering with the advancing

a man may avert the evils of the earthquake, in like manner as all others incident to his estate, by his application of forethought, and knowledge to subjugate by skill, labor and observation.

PETROLEUM.—Crude petroleum went down to 63½ cents a barrel, Saturday last, the lowest point ever reached at New York, and refined oil is worth only 7¼ cents a gallon. The average price of the crude product last year was \$1.37 a barrel; the highest price ever paid was \$20 a barrel, in 1860. The cause of the present depression is the enormous average yield of 54,000 barrels a day, against 50,000 in April, 48,000 in March, and 40,000 a year ago.

'Mechanical Interests' of the Coast.

There is no industry so intimately connected with mines and mining than the mechanical necessities of this coast. The immense deposits of precious metals continually being developed and discovered require the aid of perfectly working machinery such as can be properly furnished by our own manufacturers. Recent statistics declares that the annual demand of the world for the precious metals now falls short by \$160,000,000. This decrease of 20% in our own productions is felt not only here but in the East, and in seeking for the cause a cure has been proposed by Eastern machinery builders. It is a truth which every business man now knows, that Chicago and St. Louis are not only making strenuous efforts to compete with San Francisco, but notably in Arizona and Colorado have actually forestalled our markets. The facilities for manufacturing ought not to be greater in the East than here, besides our mining characteristics have developed a scientific knowledge of the needs of mineral regions, such as the Eastern manufacturer cannot possibly have except in theory. It certainly cannot be said that the intelligence or business policy of our coast is less than that of the East, yet with the enormous quantity of rich mineral within our reach and waiting for us to work it into bullion, the East steps in and proposes to monopolize a business which should be kept here at home. If the movement should be successful and trade in machinery be diverted from San Francisco, that interest here will languish and become subsidiary to the monopolizing tendency of Eastern manufacturers. Already Philadelphia sends her machinery to all quarters of the globe, taking advantage of our weakness for big trees and monstrosities in fruits and vegetables to undermine an industry which if not the only element of what is to glorify our future, is at least the main element. Floundering in the mud of stock gambling, this very foundation of our future prosperity is quietly slipping from under us, not without our knowledge, but without our interference. It is perfectly legitimate for us to fear whatever will tend to injure our present and future, and when we say that Eastern efforts are succeeding, we would inculcate the idea that unless we awake from our sloth and put forth such efforts as San Francisco alone knows how to put forth when aroused to the necessity of action, our slumber will be eternal in the direction of our mechanical interests.

The old pan and rocker idea of gathering the precious metals has passed into oblivion, yet it would seem as if the bullion product of our mines was believed to originate in the old-fashioned easy way. Expensive and perfect machinery is now required, and the whole world sees it, and seizes the advantage offered by a non-competing locality to our detriment. It may be useless to talk about this matter, for "no man is a prophet in his own country." The facts remain nevertheless that other manufacturers are gradually establishing a market which will draw to the East other industries, and deprive us of opportunities that are now within our reach and retention. It is not jealousy that induces us to point to the facts, but a laudable desire for local interests which all men feel. It is well to be cosmopolitan in talk, but then ideas do not build up trade and commerce.

SUB-TREASURER SHERMAN has shipped \$17,000,000 in gold coin to the East as third-class mail matter during the past eight months. Lately the shipments have been made under a government frank, and without cost.

ADVICES from Guaymas indicate that the early building of a railroad from that point to El Paso or elsewhere is unlikely, the Mexican government preferring fighting to improving.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Shasta County.

EDITORS PRESS:—At Mad Ox, seven miles above Whisky Town, we find the quartz mill owned by Messrs. Grotafend, Brickford & Co., in fine running order, with its double turbine water wheel, from A. Myers, San Francisco. The mill is running day and night, the parties are confident of a good thing in their mine, which is well located with a large body of fine-looking quartz now in sight. The extension of this mine known as the Peckham mine, now owned by A. Saulan, Warfield, Scott & Co., is turning out a large amount of good quartz, worked by an arastra, pays from \$100 to \$140 per ton, ledge from 3 to 5½ feet in thickness.

On Mad Mule

Mr. Banghart is working his seam diggings very quietly, but with satisfactory results. Since 1866 he has his new tunnel in 500 feet, and is within a few feet of his pay chimney, or seam, which is very rich. Ex-Sheriff Jackson is working the extension with good prospects. The diggings have been very rich in the gulches in this vicinity in past years.

The Bell & Knox mine on Grizzly gulch, in same district, has yielded a large amount of gold during the past two years.

The mining interests around French Gulch are very encouraging. Messrs. John, Souter, Simes & Co. are getting the old Washington mill and mine in running order again, as they have found new bodies of ore. The quartz in this district is gold bearing. F. McConnell and H. Dorr have a fine prospect higher up the mountain, their ledge is between slate and porphyry, rock averaging from \$40 to \$70 per ton, worked by an arastra right at the mine. V. Kern is also running an arastra on the north fork of the creek with equally good results.

Passing over the mountain at an altitude of 4,100 feet (into Trinity county), we find Deadwood gulch, on which five arastras are now running—George Keine, two; G. F. Deiner, two; Waver Sebastian, one. Mr. Willey and Mr. Davis are also working very rich ore from their mines. Ores in this district run from \$70 to \$120 per ton, and some has run even higher than that. There is no doubt but this will prove a fine district, it is well located, formation elate and porphyry, the same as French Gulch district, and the gold of good quality. B.

Chrome Mines in San Luis Obispo.

EDITORS PRESS:—On the afternoon of Saturday last I had the pleasure of visiting with an acquaintance the "chrome" mines among the hills about eight miles distant. For about five miles the road leads through a picturesque valley, watered by a perennial stream which is fringed with a rich growth of grass and sycamore trees. In passing through we noticed evidences that more than one picnic party had practically appreciated the inviting expanse. On leaving this valley we ascended the "grade," which is a road cut along the side of the mountain somewhat spirally, and is of just sufficient width for one team only; though there are "bays" here and there for the convenience of teams passing one another. Where the "grade" was steepest and narrowest, and in every uncomfortable way most suggestive, the hill bore nothing to which in an emergency one could cling but wild oats; above this there was a thick chaparral growth interspersed with pines and cedars; here too were some large manzanita bushes whose stems were 10 or 11 inches in diameter. Having attained the highest point, and seen four Chinamen just beginning a new mine, we returned, and on the way halted for water at the house of Mr. Louis G. Flores, of San Luis Obispo, who owns the mines and a large area of land. We were fortunate enough to find him at home, and he at once offered us his hospitalities. Having refreshed ourselves and the horses, Mr. Flores conducted us to his most productive mine. Here we found men at work in a tunnel running about 200 feet into a hill. Mr. Flores described to us the characteristics of the chrome ore, and pointed out the dips and leads of the various veins, and showed us one vein that had increased in breadth as the miners followed it, until it developed into a huge subterranean mound of pure chroma. The ore is sorted, screened, and then hauled to the depot of the S. L. O. and S. M. V. R. R., whence it is taken by rail to Port Harford, thence to Baltimore by way of San Francisco. The only factory in the country, for using this chrome ore at present, is at Baltimore. The price paid at the depot here is \$8 per ton, which, in the opinion of those qualified to judge, is not a sufficient compensation. We returned home after an enjoyable trip. C.

San Luis Obispo, Cal., June 16th.

Great Western Quicksilver Mine.

EDITORS PRESS:—Among the first, if not the first mine now being worked for mercury, is the Great Western, near Middletown, in Lake county, which has for several years been under able management of the experienced mining engineer, Andrew Rocca, now running a force of 250 men. The mine discharges the ores by tunnel and trains of horse cars right at the furnaces and assorting sheds. The tunnel for main discharge is now in a distance of half a mile. There is also a tunnel discharging through the mountain on the west side to another furnace there. The principal extracting of quicksilver is done by one fine-ore furnace of the capacity of 13 tons in 24 hours; and three coarse-ore furnaces, each of capacity of 35 tons in 24 hours. Of the coarse-ore furnaces, two are Greene's excellent furnaces; one of Coult's—patented in 1867 by Joseph Coult, then of Pope Valley, but now in Texas. This furnace gives the best, easiest and cheapest results; does not cost one-fourth as much as the others—\$5,000 will put up two of them with condensers. The line-ore condenser uses a Livermore condenser. Uses Hercules Giant powder as the best and safest—have tested all kinds—using about \$600 worth per month; average about 160 shots or blasts each six hours.

Mr. Rocca is a progressive man and has introduced many new, original and practical ideas in his various machines. His glass-roofed condensers are proving a perfect success. The flow of metal from the furnaces has not ceased for the last three years, yielding 500 to 600 flasks per month, or about 7,000 to 8,000 flasks per annum, which is sent by freight trains to Calistoga depot at \$6 per ton over Lawley's toll road. Men work 10-hour shifts from 7 A. M. and 6 P. M., and from 7 P. M. to 6 A. M.

The Sulphur Bank and Oat Hill mines are doing well, but not working up to full capacity. The latter mine is considered an excellent mine and under very successful management.

Dr. Baker, below the lake six miles, is doing well for the amount of capital now at his command. He claims some successful improvements in furnace and condensers, and deserves ample success for his great perseverance where capital was lacking. B. W. C.

Middletown, June 9th.

The Telluride Ores of Gold.—No. 4.

(Thesis by RUSSELL L. DUNN, College of Mines, University of California.)

Special Processes.

Smelting with copper ore usually more or less auriferous and argentiferous to a copper matte. This is the process employed at the Boston and Colorado works at present. When first introduced the Ziervogel process was used to part the gold and silver from the copper; this, it is said on account of the expensiveness of the chemicals employed, was abandoned. Since then a secret method, invented by Prof. Pearce, has been used, and is claimed to give better and cheaper results than any other yet applied. The Boston and Colorado works have treated the greater portion of the telluride ores of Colorado.

Smelting with auriferous iron pyrites to an iron matte. This process, so far as I have information, has never been used with telluride ores, though recommended.

Smelting with lead ores to base bullion is often used and seems to be fairly successful. Very rich ores are not usually treated by this method. The process is in use in Boyd's smelting works at Boulder City, Colorado, on ore too poor in gold and silver to be smelted in a lead bath. The base bullion can be refined and parted by the usual methods. As compared with the Copper Matte process described above, it is said not to give as high a percentage of return.

Smelting in a lead bath. Into a test of melted lead very finely pulverized ore is fed in quantities of from 10 lbs. to 15 lbs. at a time. The slag is skimmed off from time to time as it accumulates in excess; as soon as the lead is sufficiently enriched it is removed and a fresh charge of lead introduced. The refining and parting of the enriched lead are done in the usual way. The same lead can be used over and over again, the unrecoverable loss being small. This process is in use in Boyd's works at Boulder city, Colorado.

Mr. Boyd has patented what he considers an improvement by which the ore as it is fed into the test is forced beneath the surface of the melted lead and retained there until the tellurium minerals are decomposed and the tellurium driven off. Theoretically the principle seems good, how it works practically I am unable to say as accounts vary.

Rich ore are sometimes smelted in crucibles with litharge and reducing fluxes. A high percentage of metal is of course returned, but at a proportionately higher expenditure.

All of the crucible, and the cupellation lead bath processes are quite costly, and with the exception of the latter only suitable as experimental processes on a small scale. None of them, except under favorable circumstances, can treat other than high grade of ore.

The matte processes are the best on a large scale. For them and for furnace processes in general the telluride ores should not be crushed

too fine. At the Boston and Colorado works at Denver, the ore is crushed by steel rolls so as to pass through sieves of 10 holes to the running inch. For cupel and crucible processes the ore must be finely pulverized. The table will show where smelting is and can be applied.

Amalgamation.

Very little need be said about this branch of the metallurgy, as telluride ores will not amalgamate. Amalgamation is decidedly the best treatment for gold ores where it can be applied directly to metallic gold in a finely divided condition. No other method will yield so high a percentage of the gold in the ore at so low a cost. But mercury will not decompose tellurides so as to amalgamate the gold and silver in them. I am informed that the mercury cuts up and blackens, acting very much as with base metal chlorides and sulphates. In attempting to mill some extremely rich ore from the Stanislaus mine in California, it was found that only from 5% to 10% of the gold was saved; attempts since made in Colorado have succeeded no better.

Where there is much free gold and few tellurides and sulphurets in the rock, it is possible to crush the ore wet, run it through the amalgamation plant, and thence to concentrators which will save the tellurides and sulphurets and concentrate them to second class ore. I know of no instance in which this process is employed at the present time, and from general principles it is only to be recommended in the case cited above, where it is obviously more economical.

Roasting.

The roasting of telluride ores is the most interesting as well as the most important point in connection with their metallurgy. It is true that roasting is now practically abandoned on account of the large loss of metal by volatilization, but if some economical mode were discovered by which the ore could be perfectly roasted without loss, it would become used to the almost entire exclusion of smelting. Roasting is the only economical way of preparing mineralized gold ores for amalgamation. All kinds of furnaces have been tried on these ores, reverberatory, Bruckner's cylinders, and in fact almost every roasting device which the ingenuity of the metallurgist could invent, and true far, none of them, judging from the length of time they were used, are more than partially successful at the best.

The principal reason why roasting has not been successful is the volatility of gold, and in a less degree silver, with tellurium and tellurous acid. Mr. Kustel, who in 1865 said that the ores could be roasted in a reverberatory furnace successfully, made some experiments on ores from Colorado a few years ago. He roasted them himself in the sulphuretted roasting furnace connected with the chlorination plant at Grass Valley, paying the most careful attention to the rate of roasting and the regulation of the draft, and the best result he was able to obtain showed a loss by volatilization of 9%.

This peculiar volatilization of gold is one of the unsolved problems of chemistry. It is said to occur in roasting sulphurets, but some careful experiments by Mr. Kustel convinced him that in this case the loss was mechanical and caused by a too rapid roasting. Arsenic and antimony seem to have more or less of the same power (doubtful) of causing gold to vaporize. It is, however, most marked with tellurium. Whether the gold vaporizes as gold or volatilizes as a telluride of gold has not yet been discovered, but the latter supposition would seem to be the most probable, although it may be both. Gold is slightly volatile at high temperatures. A rather curious instance of this property occurred in the Boston and Colorado works at Black Hawk, Colorado, several years ago. In breaking up a hearth from a reverberatory furnace used for roasting iron matte, flakes and wires of pure bright gold were found in the quartz bed at some distance below the surface of the same. How the gold got there from above is a mystery even under the supposition (most probable) of vaporization and condensation.

It is necessary that telluride ores should be crushed dry and very fine for thorough roasting. The usual plant for roasting and the method of carrying on the process are the same as are used for roasting ordinary auriferous iron pyrites, only considerable more attention must be given to the manipulation, as the roasting is much more delicate. As the ordinary roasting furnace is well known, it is not necessary for me to give any description of it.

Willard's furnace is peculiar both in construction and manner of working. Heat is applied to the exterior by a fire underneath, and the roasting goes on inside supported by sawdust or some other finely divided carbonaceous matter which is mixed with the ore. A blast is used to supply air to the inside of the furnace. The roasted ore can be treated in three ways, viz., dry amalgamation, wet amalgamation and chlorination. By the first more or less gold and floured amalgam are unavoidably lost. The fineness of division of the gold and silver is so extreme that the particles are liable to remain suspended in water and pass off with the slimes in wet amalgamation. By chlorination the silver is of course lost unless another process be subsequently employed to save it.

Roasting processes as a rule can treat equally well all grades of ore, but the richer the ore the more careful should be the manipulation.

Chemical Processes, Etc.

Under this head I include all of the so-called wet processes which have or can be applied in reducing telluride ores. I can learn of no in-

stance in which any of them have been applied on a large scale as practical processes. Acids have been used to dissolve out the tellurium, after which it was easy to extract the metal. Such processes are, however, far too costly for any but the richest ore.

Mr. Stewart made some experiments, or rather tests, with his modification of the Hunt and Douglas copper reduction process, at Georgetown, Col. They were on a small scale, but he claims successful. His process will treat ore of any grade without previous roasting.

Concentration.

It is found unprofitable to work low grades of these ores by smelting raw, and it is therefore necessary to concentrate first. By concentrating it has been made possible to reduce all rock coming from the mine with as low a value as \$15 or \$20 per ton.

The thorough concentration of telluride ores is somewhat difficult. Owing to the complete dissemination of the small particles of mineral the ore must be crushed very fine, and then of course more or less will be lost in the tailings and slimes from the machines. Also in crushing fine, the brittle mineral is powdered, while the gangue remains in comparatively large particles—that is, the gangue and mineral are not crushed equally, thus making a preliminary sizing of the crushed ore necessary, with the use of the usual machines. It can be readily seen that the German methods, sieving and jigging, are not applicable to such fine ore. The ordinary modes of concentration employed in California and on the Pacific coast for sulphurets are much better. Biddles, cradles and blanket-boxes all do good work, though by no means as perfect as can be desired. A machine has been in use in the last few years in the Telluride district of Colorado, which seems to do better work than any of the others. It is called the Frue Vanning machine or ore concentrator. It consists of an endless rubber belt moving upward by the revolving of the rollers on which it is stretched. A rapid lateral vibration is given to it by steel springs. The ore and water are fed continuously on the surface, and the tailings discharged at the foot, while the concentrations are washed off in a box filled with water, through which the belt travels. The machine is perfectly automatic in action, hand labor only being required from time to time to remove the concentrations.

As regards the absolute efficiency of these machines (i. e., the percentage of the mineral in a given grade of ore they will save), accounts differ. The last described would seem to be the best, as the others have been discarded almost entirely for it. Even it, however, would not seem to be all that is desired, from the fact that it will not treat economically as low grades of tellurides as of other gold ores.

Very little more remains to be said of the beneficiation, except to note that there is still room for improvement. It has been noticed by smelters that certain fluxes, more particularly limestone, seem to reduce the volatilization of the metal, and it is possible that some substance may yet be found which will have the same influence in the roasting furnace. In wet processes we may find the true method of working these ores, but roasting, with amalgamation or chlorination are at present the most available for improvement.

[Concluded.]

The Treatment of Auriferous and Argentiferous Pyrites.

The trouble experienced in dealing with "sulphurets" is so well known that it will be unnecessary to say that every new method which will serve to reduce the cost and the losses of extracting gold, silver and copper from ores running high in pyrites, deserves attention. A recent modification of known methods is that proposed by Mr. W. A. Dixon, who has made a series of experiments to test its value, so far as laboratory work can accomplish that object. He roasts the ore on a matte smelted from the ore in a muffle roasting furnace, and utilizes the sulphurous acid formed for the manufacture of a dilute sulphuric acid, in suitable combination chambers and condensation towers. Any arsenious acid formed is deposited in a flue previous to the gases entering the combination chamber. So far the process does not in any way differ from existing methods. Before being discharged from the muffle furnace the roasted ore is mixed with a proper amount of coal dust or any other carbonaceous matter, and then it is transferred to a reverberatory furnace, in which a reducing flame is maintained. This reduces the oxides, formed in the preliminary roasting, to metals. The material is then charged into vats, where a large portion of the iron is extracted by means of the acid solution from the towers in the shape of a sulphate. The residue, which contains free gold and silver, is amalgamated. If copper is present in considerable quantities, the process is somewhat modified. The ore, after having been roasted in the muffle furnace, is lixiviated with an acid solution of copper, and then with water. The residue is mixed with carbon and treated further in the manner described. The process is claimed to possess the advantage of suffering less from poor roasting and of being conducted at a low temperature, with its attendant decrease of cost of fuel, of plant and of loss by volatilization. There is none of the expense connected with chlorinating roasting nor any outlay for precipitants.—Iron Age.

MECHANICAL PROGRESS.

Cable Towing.

This Belgian cable towing system, which has been used for years on the canals and rivers of Europe, and which has given very satisfactory results on a short section of the Erie canal, is now about to be introduced on this water-way on an enlarged scale.

The following are the special features of this system: There is provided first a wire rope, which is laid down along the bottom of the canal the whole length of the course, and attached at both ends. The tow-boats (or tugs), each of which is to draw its fleet of boats, are provided with engines for giving motion to the peculiar feature of the system, namely, the device known as the "clip pulley." This is a large drum provided on its periphery with a series of movable jaws, forming a continuous groove for the reception of the wire rope. These movable jaws are so contrived that they successively close upon the wire rope as the drum revolves, and clutch it with a force directly proportioned to the amount of strain brought upon the rope by the weight of the tow. Any slipping of the cable is thus prevented—the tightness of the clutch of the pulley being automatically regulated by the amount of the load. In operating the system, the cable is raised from the bed of the canal, placed in the groove of the drum, which (provided with suitable guiding and tightening pulleys) is usually placed on the deck of the tug near the bow, and the engine being started, the tug pulls itself along, and its fleet of boats in tow, by means of the cable, which it draws up at the bow, and pays out over the stern, where it falls again to its place at the bed of the canal. The record of the short section of 42 miles, from Buffalo to Middleport, which has been tried in this country, is reported to have been most satisfactory. The speed "was three times greater than the average of animal power, although seven times the amount of freight was hauled by the cable-boat." The largest tow consisted of seven canal-boats, loaded with 1,499 tons of coal, the equivalent of 150 car-loads, and the mechanical operations of the drum is pronounced to have been in every respect admirable.

ELECTRIC CAR SIGNAL.—A trial will soon be made of a new signal recently patented by Mr. I. A. Sherman and Mr. C. E. Mees, of Louisville, Ky. The first named gentleman is an accomplished electrician, and connected with the Louisville & Nashville railroad. The invention consists in combining a signal device upon the locomotive with two conducting wires extending through the cars of the train, and terminating at the end of each car in adjacent contact plates, forming seats, together with a flexible cable having two insulated wires terminating in metal plates separated by a soft rubber block, to continue the circuit, but permitting it to be broken when the cars separate, and transmit a signal to that effect to the engineer. It can be applied to freight as well as passenger cars. The cost will be something more than that of the system now generally in use.—*Nat. Car Builder.*

APPARATUS FOR FEEDING BOILERS.—Signor Chiazzari, of the Alta Italia railway, has recently described a new apparatus for feeding the boilers of locomotives and other non-condensing engines with water heated to within a few degrees of the boiling point. The apparatus consists in bringing the feed-water in a finely divided spray into contact with a portion of the exhaust steam during its passage through the feed pump, and of an automatic arrangement for shutting off the supply from the tender the moment the regulator is closed, thus preventing the admission of cold water to the boiler. Mechanically, the pump appears to be successful, as it has worked without trouble since January, 1876. Economically it seems to have answered, for the saving in fuel, in a trial of four months, is said to have been very large.

A new process for the production of a superior artificial stone is described to consist of the employment of a thorough mixture of six parts of fine sand and one of slacked lime, which is exposed for about three days to a high temperature under a pressure of some three atmospheres. The result is affirmed to be the partial decomposition of the silicious particles with the formation of silicate of lime, which acts as a cement, so that the mass, when cooled down to the ordinary temperature, hardens. This hardening process is said to continue for some weeks after exposure to the air, and the final product is declared to be as hard and solid as good sandstone.—*Mining Journal.*

GAS ENGINES.—The introduction of gas engines, says the *Engineer and Mining Journal*, has attained to remarkable dimensions in Germany and England (especially), where engines of this class, as high as 30 to 50-horse power have been built. Mr. Robert Grimshaw, reporting upon a recent visit to the Gasmotoren-fabrik, Deutz, notices that a 50-horse power gas engine, for a beet-sugar factory, was in course of construction there. The gas companies, in view of large consumption, furnish gas at very reduced rates for such engines.

THE LATEST TELEPHONE.—At a recent meeting of the Society of Telegraph Engineers in London, an interesting feature was the disclosure made by Major Webber, R. E., to the effect that he had recently experimented with a remarkable new carbon telephone from America, which owed its power to a diaphragm of animal tissue. With this instrument, which was not further described, Major Webber was able to speak in a low tone over 70 miles of wire with perfect clearness. A part of this line consisted of underground cable, in which from 20 to 30 other circuits were busily at work without interfering with the telephonic message. The voice of this instrument was singularly full and life-like, whereas that of magneto-telephones is peculiarly thin and parrot. This experiment is completely cast in the shade by the successful working of an ordinary telephone perfectly through 195 miles of wire. This was accomplished by Lieut. Roade, of the United States Military Telegraph, between San Diego and Fort Yuma. The old-fashioned telephones of years ago had a diaphragm of animal tissue and could be used at remarkably long distances without any magnetic current at all. It is now very certain that the power of the telephone to transmit vibrations does not depend on the diaphragm so much as upon the medium which transmits them, and even now diaphragms are being dispensed with. So Major Webber has not discovered anything very new or curious.

EUROPEAN STOVES.—In Russia, Sweden, Norway, and all Northern Europe, stoves are usually built of brick, covered with porcelain and placed while building in the house. They are of the size of a large and very high chest of drawers, and usually stand in the corner of the room. The fire is burned in a furnace near the bottom, and the heated smoke is made repeatedly to traverse the structure from side to side, along a winding passage, before it reaches the top, where a pipe conveys it, now comparatively cold, into a flue in the wall. The heated mass of brick continues to warm the room long after the fuel is burned. It is generally sufficient to warm the stove once a day. The same quantity of wood or turf burned in an open grate would be consumed in an hour, and would hardly be felt. There is one of these stoves in every room.

WIREBOUND SHEAVES AND THE MILLERS.—The millers of the Western States of America have set themselves against the use of wire-binding reaping machines on the ground that the wire gets into the flour and oil, and injures the milling machinery. The Minnesota millers have agreed not to buy wheat that has been bound with wire, except at a reduction of 10 cents per bushel. As nearly all the self-binding reapers of America bind with wire, this proposed action of the millers is a serious one for the farmers, and for the makers of the American sheaf-binding reaping machines. It is doubtful, however, whether they will have power to carry it into effect. No string-binder has yet been uninterruptedly successful in ordinary field use, though two or three are now before the public, and will probably be perfected after another harvest.

CAR HEATER.—Mr. John Somerset, of Manchester, Eng., has invented a heating apparatus for railway carriages. Inside the smoke-box of the locomotive is a coil of pipe connected with a trumpet-mouth in front, so that as the engine travels, a current of air is forced into the coil, where it is heated and conveyed by pipes to the train. Each carriage is fitted with a series of pipes passing under the seats of the several compartments. The connection between the engine and first carriage, and between the other carriages, is by means of a telescope sliding tube and hall and socket joint, so that the train can expand and contract and pass curves without breaking the connection. The rear end of the tube is open, so that as the train travels, a continuous current of hot air passes from one end to the other.—*Car Builder.*

WORKING STEAM AT HIGH PRESSURE.—It is well known that great efficiency in steam engines is obtained by an increase of pressure and the use of expansion. To accomplish this, the point lies not so much with the engine as with the boiler, engineers finding no difficulty in working an engine with steam at 150 to 200 pounds per square inch; therefore Mr. Walt, an eminent Liverpool engineer, thinks there is no limit to the practical working pressure. Some engineers will be inclined to differ with this opinion, as the management of steam used expansively in simple reciprocating engines at ranges of pressure much exceeding those named, is considered by many risky practice.

STEEL-FACED IRON PLATES.—A cast-iron mold is divided into two sections by means of a transverse plate of thin sheet iron. The two metals are then poured into the respective compartments. The sheet iron partition prevents the mixture of the metals and facilitates the welding by itself being brought into a state of fusion. It is said that the product is well adapted for safes, and that it resists drills.

SOFT STEEL BEING USED FOR TIN PLATES.—A correspondent of the *London Mining Journal*, who appears to be well informed, states that very large quantities of tin plates made from steel are branded charcoal and best charcoal, and so exported, and these plates, he affirms, are exceptionally well received, especially for stamping purposes, in the United States.

SCIENTIFIC PROGRESS.

Centrifugal Force and Fly Wheels.

It is not always that practical men are willing to admit the value and importance of scientific knowledge as regulating the operations and accidents of a workshop. We had a valuable incident of the kind that forced itself upon our notice, says a foreign contemporary, a few days back. A large pulley or rigger, three feet in diameter, and very wide, was split across its rim by carelessness in unloading; at the same time it was noticed that two of the arms out of six were cracked by contraction in cooling. In order, however, to save expense it was proposed to patch the broken rim of the pulley with wrought-iron plates, which was done. *Per se*, the iron plates were stronger than the original casting, but the whole weight of the patch amounted to about 15 pounds. As the pulley revolved at the rate of 600 revolutions a minute, this unbalanced weight on the rim became by calculation as much as $\frac{7}{8}$ cwt. radial force outwards. This scientific result was brought to the knowledge of the practical men, but they could not see why the pulley would not do very well if the patch was as strong as the rest of the rim. The pulley was accordingly run under protest, and hardly had the maximum speed been attained before the pulley flew in pieces, and might have been dangerous to life and limb. The pulley, undoubtedly, broke, as above indicated, by centrifugal force, which, by the unbalanced patch of 15 pounds, caused a breaking radial pressure outward upon the broken rim at the position of the patch of $\frac{7}{8}$ cwt. This was quite sufficient to break the rim outward with enormous force, so that the pieces flew about the shop like fragments of a hursting shell. It will be well for machinists to remember this incident when they have occasion to repair fly-wheels.—*Scientific American.*

UNDERGROUND TELEGRAPHING.—Two systems have been proposed. In one, known as the Alberger plan, tubes of glass are prepared of a convenient length and about one-eighth inch internal diameter, in which a steel wire is introduced. This compound tube is then inserted in an iron one, the whole brought to a welding heat in a furnace, and then rolled, reducing the iron pipe so as to make a solid mass of pipe, glass and coating. The coating of iron acts as a shield and an arrester of induced currents. The wire being perfectly insulated is capable of working to a higher capacity and with less resistance than any other system. The wires are buried in the ground, a battery attached to the first piece of pipe and the pieces connected by the ordinary telegraphic tie—testing with a galvanometer as the work progresses. A bell-shaped sleeve somewhat larger than the pipe is drawn over each joint when connections are made, and an insulating fluid poured into the sleeve through an orifice in the center, thus making a joint impervious to moisture and perfectly insulated. The second system is the invention of David Brooks, the well-known electrician. The wires wrapped in cotton, 20, 30 or more are placed in an iron pipe, and after being laid in the ground oil is introduced and allowed to run its entire length, the source of supply being an elevated vessel always kept full so as to keep a constant pressure on the oil already there. These pipes have been laid in Philadelphia. The strong point in their favor is economy. Any number of wires may be enclosed in a small space, while the work of laying them does not involve much expense. Once in place they are free from disturbances of all kinds.

PREHISTORIC REMAINS IN OREGON.—The coast of the Pacific ocean some distance below the mouth of the Columbia and above, even to the colder latitudes, shows in its shell mounds or beds evidences of a dense population that must have long ago lived and thrived on the bounteous sea-food that the ocean provides. Up the little streams and inlets may these beds also be found. Excavations made at Clatsop beach, Oregon, show a depth of six feet of shells, human bones and skulls without having reached the original dirt stratum. The length of this bed is unknown and its age can only be imagined. It is in shore half a mile, and in ancient times must have been the beach proper. Ages have passed since these wild people encamped by the booming waves, for immense old firs, five and six feet in diameter, are growing over the giant trees that preceded them. No implements of any kind have as yet been found in these beds. It is said that similar beds are found on the Alaska coast, also remains of ancient junks.—*American Antiquarian.*

LOCATION OF THE GARDEN OF EDEN.—Of the four rivers which encircled the Garden of Eden in Genesis, the Phrat and Chiddkel have long ago been identified as the Euphrates and Tigris. A cuneiform monument in the British museum has a series of geographical names, and among them occur Pisan and Guchan, both canals of the Euphrates. Pisan was a canal running south of the Euphrates, and in the epoch of Alexander the Great, went under the name of Fullakopas canal; it is the Pisan or Pischon of the Bible, and Guchan is the Gihon. The Hebrew people had therefore placed the cradle of the human race in the vicinity of Babylon.

Fuel-Gas from Water.

Much attention has recently been directed to the Lowe & Strong processes for producing a cheap gas by the decomposition of water, which in the form of steam is brought in contact with incandescent carbon. The experiments that have lately been made in Sweden and Russia have been attended with favorable results, and several scientific men, some of them government officials, declare "that the gas has by us been employed for welding wrought iron, for smelting in crucibles as well as pig iron as steel; that the results of these experiments have been very satisfactory as to the heating power of the gas. On the other hand, we can confirm the statement that the employment of the gas for cooking purposes causes extraordinary saving in the household department, and that the cleanliness and convenience of its use must make it a favorite with all housekeepers."

The gas was used in a small baking and roasting stove, which required a gas consumption of only fourteen feet an hour, maintaining a constant heat of 275° centigrade.

For illumination the gas was conducted through a vessel filled with cotton moistened with benzine, and the result was eminently satisfactory.

TELEPHONES WITHOUT DIAPHRAGMS.—M. Ader reports some experiments confirmatory of the views of Du Moncel, upon telephones without diaphragms. He has often observed that the reproduction of words and sounds, which are occasioned by the interruption of currents, can be made in these telephones with a different quality, and upon a higher or lower pitch, according to the degree of tension which is given to the iron wire; but if the fundamental sound of the wire is muffled by holding it between the fingers, the sounds which are reproduced become dull, a little more feeble, and always in the same tone. He concludes from his experiments, that the sounds which are produced by a magnetic nucleus are probably the result of shortenings and lengthenings of the wire, determined by rapid magnetizing and demagnetizing, the molecular vibrations of the magnet producing the effects of the telephone, and the iron diaphragm only strengthening the vibrations, and rendering them more sensible to the ear by its own vibrations. We know it is possible to replace the iron plate of the receiver by non-magnetic substances, as a plate of copper, glass, wood and even card-board. The magnet does not exercise any particular action upon the diaphragm. The mistake was not in the fact but in the cause, the substance of the diaphragms receiving the molecular vibrations and communicating them to the ear.

THE HELIOGRAPH.—Devices for signaling, very similar to the heliograph or "sun writer," have been in use for ages. As far back as the Persian invasion of Greece, polished metal surfaces were used to flash the rays of the sun and give warnings of one kind or another. The signaling in this and other cases was, however, imperfect, and could not be carried on over a space of more than 18 miles. But the instrument now in use, the Mance heliograph, is a great improvement, for it not only concentrates the sun's rays but it flashes them with the utmost precision to any required spot, irrespective of the relative location of the sun. It is also provided with a finger key, so that flashes may be made of long or short duration, thus permitting the employment of the Morse telegraphic alphabet. Under favorable conditions intercourse has been carried on through the medium of two of these instruments over a distance of nearly 100 miles, and at several points occupied by the English army in Afghanistan, regular communication is maintained at distances of not less than 50 miles by heliographic signals. The instrument weighs only seven pounds and can be carried and worked by one man. It is, of course, useless in cloudy weather. It has already been proposed to establish a systematic telegraphic communication between various islands in the West Indies by this process, and before long it will be adopted as a means of signaling between vessels when at sea.

NEW USE FOR PAPER.—A great diversity presents itself in the various useful purposes to which paper, or *papier mache*, has been applied of late years. Besides ornamental articles, clothing, hedding, stamps, boxes, barrels, picture frames, furniture, stovepipes, chimney-pots, bricks, partition walls, carriage and car wheels and hoats, it would seem as if the inventive ingenuity of manufacturers has succeeded in adapting this single substance to some new use every day. The last remarkable application of *papier mache* is the manufacture of a revolving dome for the astronomical observatory of Prof. Greene of the Polytechnic Institute at Troy. This dome has an internal diameter of 29 feet, and if constructed in the usual manner, would weigh five or six tons and require powerful and complicated machinery to manipulate it, besides also requiring foundations of considerable depth for its support; whereas the total weight of the paper dome will not exceed a ton and three-quarters, and, mounted on pivots working in iron grooves, is capable of being revolved in any direction required without the assistance of any machine or apparatus of any kind. The paper is put upon a light framing of wood, and is, by means of a special preparation, rendered fully as hard and even more rigid than wood.

The Mining Share Market.

The mining share market during the past week has not been of a kind calculated to gladden the heart of the average operator, nor yet inspire the masses with hopes of an early improvement. Comstock shares, the old king pins, have been soggy, resolutely slipping down in spite of determined efforts to maintain previous quotations. That stocks should be neglected on the approach of our great national holiday is natural enough, the dealers patriotic instincts getting the better of selfish considerations.

Glancing over the field our mining industries seem fairly prosperous, notwithstanding statistics show the yearly supply of the precious metals to be \$160,000,000 less than the business of the world demands. This is a deficiency which our mines could fill. The bullion yield, although short in Nevada to the extent of 20% this year, as compared with last, need not be regarded as a giving out of the mines. Reports from all quarters show an unusual activity in mining, and an increase in the quantity of metal turned out. The glowing accounts of recent strikes in Mono county, Cal., in Arizona, Idaho, and Colorado, though probably exaggerated, are no doubt in the main truthful, pointing to an early increase of our aggregate bullion production. The late falling off in the product of this coast has been due mainly to the diminished out-put from the Bonanza mines on the Comstock lode, which latter has greatly disappointed public expectation, both as regards the yield from these as well as other mines in that vicinity. The Comstock group of mines made but a sorry bullion exhibit last year, a showing which the present year will hardly improve, even though the ore developments now deemed imminent should prove realities. A glance at the history of these mines is not calculated to encourage investments in their shares just now, much as is said about ore bodies known to exist in the lower levels of some of them. Only a little more than one year ago, what was then proclaimed as a veritable bonanza was struck in the Sierra Nevada ground. The stock of that company, then worth \$2.90 per share, at once jumped to \$270, raising the value of the mine from less than \$300,000 to \$27,000,000. But there was no bonanza there, or none, at least, that has yet yielded any bullion to speak of, nor is it known when, if ever, it will make any large production. The price of these Sierra Nevada shares afterwards fell to \$37 per share, being at the rate of \$3,700,000 for the entire property. In less than six months over \$23,000,000 disappeared, nor is it difficult to say who were the chief sufferers by this annihilation of values. This, though an extreme case well illustrates, in a general way, the record of these Comstock mines through a long series of years, the assessments on the shares of these mines, as a whole, having amounted to more than 50% of the dividends declared, to say nothing of purchase money paid for these properties in the first instance. Leaving out dividends paid by two mines, the Con. Virginia and the California, the assessments collected from Comstock shareholders exceeds the dividends disbursed to them by more than \$15,000,000. Notwithstanding the improved prospects of these mines through the completion of the Suto tunnel, it will be time enough to discount the advantages these accruing when they come to be realized. Meantime let the magnates, who manage the Comstocks and have confidence in their future, go on and prove their faith by their works, while the public possessing themselves in patience wait and see what shall come of it.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Northern Belle, June 23d, \$2,491.71; Indian Queen, June 23d, \$4,117.07; Northern Belle, June 25th, \$2,550.81; Ophir, June 26th, \$16,656.03; Belle Isle, June 30th, \$28,000; Independence, June 30th, \$15,000; California, June 28th, \$46,074.66; Martin White, June 25th, \$5,895.39.

PLATINUM.—We have been shown a letter from T. A. Edison making inquiries about platinum deposits on this coast. The letter coming from Mr. Edison is of course written with an electric pen. Platinum has been found in small quantities in our mines, perhaps more in Butte county than elsewhere. Under the impression that it was more valuable than gold, the miners looked for it or tried to save it, but it not being a paying metal its search was abandoned. Intimately united with gold its separation is a matter of extreme difficulty. Our rocks are seldom favorable for such a metal. It is found generally in the alluvial gold of mountain streams. The unexplored mineral regions may develop platinum finds, particularly the unexplored eastern interior of British Columbia, and the west source of Frazer river, in quantities sufficient for profitable extraction.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MAHONEY.—Ledge, June 25: The new hoisting works are expected to be in running order in a few days. The boiler is 54 inches in diameter by 10 ft in length, and the machinery is estimated at nearly 100-horse power. All of it has been brought from New York. A compressor drill will also be purchased to facilitate operations in connection with this mine. The new shaft is down 50 ft.

DOWN'S.—Another clean-up was completed at this Volcano mine, on Monday of last week, embracing a run of 24 days. The yield of bullion was \$8,300, the average surrender being \$37 per ton. This is the largest amount of gold yet obtained from any clean-up of this claim, although the average yield is somewhat below that of one or two previous runs, where a smaller quantity of ore was put through the mill. The mine is looking well in every way. Shinking operations will be commenced in a few weeks.

MICHELLE.—The Moyle gravel claim, in Volcano basin, is running along smoothly, under the co-operative plan. Moyle furnishes water and two men, and the workmen of the Santa Fe claim furnish water and one man, understanding that the proceeds are to be equally divided between the owners and employers. We are unable to say how the claim is paying under this arrangement. They have cleaned up twice since this arrangement was entered into, and from the fact that operations continue to be pushed steadily, we presume the result was satisfactory to all parties. The Santa Fe claim, near Volcano, are very good, with a fine lot of bullion, which was shipped to the Bay through Wells, Fargo & Co.'s express. The Poor Bros., whose claim is above Blue Tent, have recently struck into some very rich gravel and are drifting. They have engaged water from the South Yuba Canal Co. to make a clean-up soon and expect big returns. The May bullion product of the following Nevada county gold mines was: \$42,200; Milton, \$9,000; Pittsburg, \$9,000. The Excelsior gravel mine, at Sautville, produced \$75,000. Mrs. S. H. Dikeman, of Rough and Ready discovered the croppings of a four-inch ledge in the house a few days since, and proceeded to prospect it. Alpine mines, at Monitor, in the Colorado No. 2 (Tarshish) have developed a new ore body, showing free gold and giving high assays. The same body has been struck 112 ft above the old Tarshish workings.

INYO.

MOPOC.—Independent, June 21: Results of work on 1000 level for the week ending yesterday morning, are as follows: Main tunnel run 34 ft; drift from 300-foot point, 15 ft; drift from 1100-foot point, 15 ft. Total length of tunnel, 1,730 ft. Drift, 300-foot point, 100 ft. Drift, 1100-foot point, 33 ft. Face of tunnel has just passed through clean sand, and is now in easy breaking ground. Drift at 1100-foot point presents about the same appearance as it has for the entire length. Following the hanging wall; ledge matter in top, bottom and west side of drift. In drift at the 200-foot point, broke into a small cave, lined with crystallized lime and manganese. Ground at this point looks very fine.

MARIPOSA.

COUTERTVILLE ITEMS.—Gazette, June 28: J. Handy, of San Francisco, has sold the Bonduant and Martin & Walling mines to Eastern parties for \$80,000 each. The 10-stamp mill at the former mine is running day and night on \$30-ore. James Dolan & Co. are driving a main tunnel on the vein in the Italian mine, and have a large vein of \$15-ore. Mt. Morris mine, owned by Maj. W. Burn and Johnson, is developing a vein two ft in width, that prospects in pure gold at the rate of \$20 per ton. Hill and Harford, at Big Creek, have struck a large vein of fine ore on Burnett's claim. A few tons of ore in the Bull Creek mill, paid them at the rate of \$15.37 per ton. The vein is fully five or six ft in width. In the Gen. Ord mine, the tunnel is in about 100 ft, with a vein 20 inches to two ft in width with ore worth \$25 to \$30 per ton. In the Eureka mine, the vein is fully six ft in width, and pays \$40 to \$50 per ton. On Texas hill a vein was struck, out of which nine tons were taken which yielded \$50 per ton.

MONO.

ITEMS.—Bodie News, June 25: The mining product of Bodie district is constantly on the increase. Standard has enough ore in sight to guarantee two years more of dividends, and the mine is kept in advance of the mill. Bodie is opening out so immensely rich that the one ton of ore, it is said, equals a dozen of any found elsewhere. The new strike in Lake district, in the Mammoth mine, is said to be enormously rich, and the indications are that this lead may extend for many miles. Traces are said to have been discovered far to the south and southeast. The new strike was made in the Mammoth 73 ft below the bottom of the middle tunnel. The assay reaches up into the thousands—both silver and gold. A rich strike has been made in the Orient, of a 10-foot ledge at 125 ft.

BULLION.—The bullion shipments from Bodie district, through Wells, Fargo & Co., from June 1st to 24th, inclusive, are as follows: Standard, \$138,008.23; Bodie, \$70,747.13; Bulwer, \$1,253.30; Noonday, \$9,121.27. Total, from June 1st to 24th, \$236,034.88. During the month of June the entire shipment of bullion reached about \$301,225.83. We have now a full week to run before the close of June, and the figures say that time will approximate \$300,000.

BODIE MILL.—The result of a two days' run in the batteries of the Bodie mill was shown yesterday, in a collection of gold nuggets worth \$15,000. The nuggets were mixed with the fine ore. The assay reaches up into the thousands with the metal. The stamps are crushing about 22 tons per day. The clean-up of an 11 days' run realized \$75,000. The bullion is worth about \$13.75 per ounce, with about 30% silver.

PRESCOTT DISTRICT.—The new Prescott district lies south of Bodie 25 miles, and is 17 miles long, north and south, by a mile wide, east and west. The usual belt is a strict continuation of the Bodie deposit. A large stream of water traverses the entire length of the district, and cuts nearly all of the principal ledges obliquely—in two instances to the depth of about 1,000 ft. The entire eastern slope is mineral bearing. The ore bodies are so large and well defined that but little of the usual sinking has been done. The assays that have been made upon the ore are as follows: Standard, \$13.75 per ounce, with 30% gold and 40% silver. One of the ledges shows a width of nearly 100 ft, mostly free milling ore.

ITEMS.—Chronicle, June 25: The north drift on the high ledge of the Standard Con. is in 200 ft; the fissure at this point is so large that timbering on the Comstock plan, has to be resorted to. The ledge is 20 ft wide of clean ore in the middle tunnel. The West side reaches up into the half of it \$300-grade. The new bonanza, Bodie, is working to its utmost. The ore in all of the levels is rich. On 300 level, the winze is down 45 ft in two ft ore. In Toga the winze on the 320 ledge, west, is down 37 ft. Ore is five ft wide. The Con. Pacific is in ore five ft wide on the 100 level. Steam hoisting works are being erected on the surface. In Bulwer the drift in the canal branch of the Kalamien ledge is in ore two and a half ft wide.

NOONDAY AND NORTH NOONDAY.—Bodie Standard, June 20: The south drift on the Noonday ledge, 200 level, is in 270 ft, the ledge in the face being two and one-half ft wide. The winze is down 116 ft, the ledge being strong in the bottom. Drifts will be run north and south from this point. The slopes are looking well. The new joint mine, up the hill from the North and North Noonday, is now 104 ft in depth, a progress of 14 ft during the week. At a depth of 200 ft it will be connected with the old Noonday workings.

STANDARD CON.—The north drift from the east crosscut, 285 level, has been extended 10 ft; total length, 253 ft. The ledge is from 12 to 15 ft wide, of very fine ore. The winze is down 116 ft, the ledge being strong in the bottom. The ledge here is also about 15 ft wide, of good ore. The west crosscut from the south drift, 450 level, incline shaft, is in 63 ft; progress during the week, 10 ft. The face is in good blasting rock. South drift, on Olden ledge, has been advanced since last report nine ft; total length, 97 ft. The ledge is two and one-half ft wide, of good milling ore. The west crosscut from the south drift, 550 level, is in 131 ft;

progress for the week, 25 ft. It is expected soon to cut the ledge in the north drift, 385 level, of main shaft. In the slopes on the Olden ledge, the ledge is three and one-half ft wide, of very rich ore. The ledge in the slopes, south drift, 300 level, is four ft wide, and looks well. In the slopes, south drift, 550 level, the ledge is eight ft wide, of very fine ore. The ledge in the slopes, north drift, 385 level, is from 10 to 15 ft wide, of good ore, and the mine the night is looking well.

SYNCRATE.—The south main tunnel is following a small vein. The tunnel has now reached a point within 50 ft of the dividing line, between the Syndicate and the Toga, where a crosscut will be run the entire width of the company's ground. An upraise is being made from this vein to connect with the drift on the old Toga ledge in the old tunnel, and is now 35 ft above the drift. The vein holds its own in width and prospects well in gold. The upraise to connect with the old winze is nearly through. The winze is being made a double compartment, one for ore chute and the other for a tramway. The chute will be 50 ft in length. A track is being laid through the old Osceola tunnel about 500 ft, from which point crosscuts will be run to connect with the Isabella on the west and the Nevada on the east. The mill is running steady on Standard ore, and will be started on Syndicate ore, the contract, when it will be started on Syndicate ore.

BONK COS.—The crosscut east from the old shaft is in 358 ft. The drift south, on first level, 63 ft. The drift south, second level, on ore 72 ft. The winze, second level, 41 ft. The east crosscut, third level, 23 ft. The west crosscut, same level, 113 ft. Drift north, No. 1, 275 ft; No. 2, 150 ft. Drift south, 115 ft. South crosscut, east from south drift, 25 ft. South winze, 29 ft. The vein in the south winze, on the third level, shows improvement in width and quality of ore, and the drift south, on second level, is improving, both in the size of the vein and its quality. In the bottom of the north winze the vein continues very rich both in gold and silver, and is becoming gradually larger. The mill is running steadily and doing very good work, and to-morrow two more bars will be ready for shipment.

NEVADA.

ITEMS.—Foothill Tidings, June 28: The Nevada City mine has struck an apparently good lead of quartz at the bottom of the incline, which is now down something like 100 ft. Perkins came down from the North Bloomfield mine with a fine lot of bullion, which was shipped to the Bay through Wells, Fargo & Co.'s express. The Poor Bros., whose claim is above Blue Tent, have recently struck into some very rich gravel and are drifting. They have engaged water from the South Yuba Canal Co. to make a clean-up soon and expect big returns. The May bullion product of the following Nevada county gold mines was: \$42,200; Milton, \$9,000; Pittsburg, \$9,000. The Excelsior gravel mine, at Sautville, produced \$75,000. Mrs. S. H. Dikeman, of Rough and Ready discovered the croppings of a four-inch ledge in the house a few days since, and proceeded to prospect it. Alpine mines, at Monitor, in the Colorado No. 2 (Tarshish) have developed a new ore body, showing free gold and giving high assays. The same body has been struck 112 ft above the old Tarshish workings.

PLUMAS.

ITEMS.—National, June 23: Two men working in the Metcalf claims on Winter creek, below Wilson point, have cleared over \$500 in the last six weeks. In addition to this, on Monday last, they found a nugget weighing about \$500—nearly pure gold and as large as a man's fist.

SIERRA.

GOLD BAR QUARTZ MINING CO.—Mountain Messenger, June 23: This mine is situated near Jim Crow canyon, Sierra county, within four miles of the Sierra Buttes mine. Already \$150,000 have been expended in its development. There are over 1,000 ft of tunnels, shafts, drifts and stopes opened and ready to work, with the exception of caves at the mouth. About 10,000 tons of good average ore is in sight; vein varies from four to nine ft in thickness, and dips east 45°. The strike is northwest and southeast; formation of walls talcose slate. No machinery is required for hoisting or pumping, and the present tunnel will give from 500 to 1,000 ft back. It is safe to say the ore will average \$10 per ton. Free gold is seen in the great mass of the ore, which is refractory to a certain extent. It can be worked by sweating (at an additional cost of \$1.50 per ton) and sample amalgamation.

TUOLUMNE.

ITEMS.—Tuolumne Independent, June 23: The Soulsby mine, in the last few days, has been uncovering very good rock. In the Hunter and Star King mines a new two-ft vein has been found, which shows free gold all through. The Spring Gulch mine improves in appearance the deeper the miners go. The Humburg & New York tunnel company's consolidated property has been sold to Moyle Bros., of Klamath, and they are now opening the old tunnel on the west side of the mountain.

TRINITY.

TAYLOR FLAT.—Journal, June 23: This flat lies on a horseshoe bend on the Trinity river in a rich ariferous gravel. The bedrock supporting the gravel is about 20 ft above the river. The gravel is from 40 to 60 ft above the bedrock. The gold scales and flakes are disseminated and evenly distributed throughout this vast area of gravel, which has been so thoroughly tested along its mile and a quarter of water front, and in the interior of the flat by shafts, that the amount of gold contained can be computed with a great degree of certainty. The very lowest estimate of the value of this gravel, by reliable men, is 15,000,000 cubic yards, of a minimum value of 50 cents per cubic yard, or \$7,500,000 gross product. This is a placer or hydraulic mine, in which water, under a high pressure, does the work, and very cheaply, too. The water is obtained from French creek, one and a half miles above the gravel deposit. The creek is fed by perpetual snows from the Sierra Nevada, and flows to the north. Three miles from the gravel the water has an elevation of 250 ft.

NEVADA.

WASHOE DISTRICT.

SUTRO TUNNEL, June 30: To-night the mountain tops overlooking the Washoe silver region and the Carson valley are ablaze with bonfires, and the echoes of cannon and discharges of Giant powder are heard in every direction. The event which is being celebrated is the final completion of the Suto tunnel, for the reception of water from the Comstock mines, after 10 years of ceaseless labor day and night, and the expenditure of \$6,000,000. The powerful engine of the combination shaft of the Hale & Norcross and Savage mines was started up this morning at precisely 6 o'clock, discharging their water into the Suto tunnel, at the mouth of which it made its appearance in 1 hour and 20 minutes, showing a temperature at least of 101°, which gradually increased to 118°. In 8 hours the water in the long drowned-out mines was lowered 100 ft. Everything worked to a charm. The wooden boxes, constructed of three-inch tongued-and-grooved Sierra Nevada pine, did not show a leak, and not even a particle of steam escaped from them, so that the tunnel, after the hot water was turned in, showed barely an increase of temperature. The water from the Sierra Nevada, Union, Ophir, the Bonanza mines, Best & Belcher, and Gould & Curry will not be turned in for a couple of weeks; and after all finds its way into the tunnel it is expected that one of the double-line of boxes will have ample capacity to carry off all the water.

BELCHER.—Enterprise, July 1: Incline has reached a depth of 50 ft below the 2760 level. East drift from the 2760 station is in 141 ft, the face showing soft porphyry. The face of the south crosscut on the 2560 level is in fine looking quartz.

CUTLER & CURRY.—East drift on 1700 level has been extended 20 ft during the past week. Total length of drift, 973 ft.

BULLION.—Incline winze from the 2150 level has been sunk a total length of 51 ft.

HALE & NORCROSS.—The 38th station has been completed. It has been re-timbered with 10-inch timbers, and enlarged so that it is now 18 ft wide, 72 ft long and 10 ft high. Repairs to the south compartment of the main shaft are progressing well.

TRAIL.—The north drift from the upraise, 2d station, has been advanced and timbered 26 ft. The rough quartz and porphyry; total length, 160 ft. From the face of the northeast drift, 3d station, drift is west 20 ft, through bright lively quartz. West crosscut, 428 ft from the shaft, has been extended 12 ft through quartz and porphyry. Crosscut, 473 ft from the shaft is in 22 ft, through quartz carrying a little ore.

SAVAGE.—Repairs have been made on the vertical shaft incline, 1640 drift, and new cylinder boilers have been put in the north air compressor.

CHOLLAR-NORCROSS-SAVAGE.—Repairs to pump shaft have been completed.

NAAGARA.—North and south lateral drift, 500 level, have been run 30 ft, following in the course of a very promising ore vein, assays from which run from \$14 to \$80. The faces of both are in porphyry, with spots of ore carrying low assays.

EXCELSIOR.—North drift on the 2400 level has advanced a total length of 527 ft.

YELLOW JACKET.—New shaft is 2630 ft deep, working level. The 2500 east drift is in 305 ft. West drift is in 244 ft. Assays \$45 to \$100. Progress in this drift is very slow, owing to hardness of rock.

EUREKA DISTRICT.

FRANK.—Sentinel, June 29: Within the past two days 105,000 pounds of bullion and five cars of fine dust have been shipped by the Eureka Con. In the haulburg the north crosscut on the 200 level has reached a splendid clay wall, along which it has been driven some distance to the northward. The main north drift, from which this crosscut was started, has been swung round to the west and has struck the same well-defined clay wall at a point 100 ft north of where it was reached by the crosscut. At this point an upraise will be made to reach the Rule winze, and at the same time the clay wall will be continued along the chry to the northward. This clay is as smooth as a plastered wall, and is perfectly regular in dip. Just inside of it will no doubt be found the ore body. Crosscutting may be done at this point at any time. The ore can be reached in a very short time after the word to advance to it has been given.

PARADISE DISTRICT.

ITEMS.—Silver State, June 30: Messrs. "Brick" Palmer, Murphy and "Big Nick," struck the south extension of the Bullion mine last week. The ledge is four ft wide, the ore looks well, and the average of five assays shows it to be worth \$155 in silver per ton. The Arthur ledge was to be worth \$155 in silver per ton. The Arthur ledge was to be worth \$155 in silver per ton. The Arthur ledge was to be worth \$155 in silver per ton.

ELKO.—The mining country northeast of Island mountain contains both quartz and placer mines, the latter of which can be made to pay about \$10 per day to the man, as soon as a sufficient quantity of water can be got upon the ground. There is an abundant supply a few miles distant from the best locations, the expense of collecting which to the mines is heavy. The quartz claims thus far, have developed nothing important.

WILLOW CREEK.—Rich ore has been found in a new opening on the Ethan Allen mine, on Willow creek. It assays \$150.67 in silver to the ton, and contains 65% lead.

PICHOE DISTRICT.

CLEAN UP.—Picchoe Record, June 21: Eight bars of bullion, valued at \$11,341.10, came up from the Dry Valley mill on Wednesday evening. This is the final clean-up of that mill, it having now closed down, and there is no knowing when it will be started up again. The immense pile of wood that used to be there is exhausted, and also pretty much all the tailings.

CHRISTY BUTTES.—The Christy mill and mining company shipped from Silver Reef, on the 14th and 16th of June, bullion valued at \$2,224.33.

PICHOE BUTTES.—Bullion to the amount of \$17,400.37 was shipped during the past week by Wells, Fargo & Co.

ARIZONA.

TOMBSTONE.—Sentinel, June 21: About \$10,000 of bullion was shipped for this mine from Tucson last Tuesday. Everything at mines and mill is working smoothly upon an ample supply of rich ore. The Contention mine has ore ready for extraction, the value of which is variously estimated at from \$1,000,000 to \$3,000,000. A 40-stamp mill is about to be erected at this mine.

PICACHO MILL.—A huge lump of retorted gold was turned out from the Picacho mill a few days ago; value, \$2,000, the product of 125 tons of ore. The quantity of ore now developed in the Picacho mine is immense, and ample sufficient to supply the 15 stamps of the mill for many years.

AJO MINES.—Work upon the old Ajo mines has been resumed on a small scale, and is already developing ore of singular beauty and of high percentage in copper. Their easy distance from the railroad, 45 miles over a good road, makes it possible to ship the ores with profit.

GOVERNOR COUNTY MINES.—The mines in Mohave county are growing in value, and the Southern mining company, some 124,704 pounds of machinery and supplies have arrived the past week, including over 2,000 pounds of powder, a fine new engine, a Blake crusher and a Davis pulverizer. The engine has a 16-inch cylinder and could work 30 stamps.

PHOENIX.—Phoenix Herald, June 25: Senor Gavilondo, of Mexico, has made rich finds in his ranch at Base. The rock is a very rich copper, about four ft in width. Assays at the mint at Hermosillo ran as high as \$4,000. Average assays made in Tucson ran about \$390 per ton.

PINAL COUNTY.—Prescott Enterprise, June 21: The Stonewall mill is now well supplied with water from the Hanning creek, and is running full time. Ore is most abundant. Another rich strike has recently been made in the mine, showing native silver. The grading for the new roasting furnace, soon to be erected at the Haskin mill, is well advanced. It is at the northwest end of the mill building on a line between the battery and pan rooms. We understand that at the depth of 150 ft a great improvement is visible in the ore body of the Independence. It is richer than the ore that has been heretofore, is more compact and more abundant in quantity. Mr. H. C. Hoffman, of McMillen, has just had 55 pounds of ore specimens worked at the Haskin mill, and as the product was 10 pounds 6 ounces of bullion, nearly 800 fine, our readers will understand that the Globe district ores are unusually rich. The specimens referred to came from different mines in the district.

COLORADO.

LEAVELLE.—Courier, June 26: The Highland Chief and Highland Mary have been consolidated. The property is valuable. In one shaft the ore is said to be 14 ft thick, and at another, 21 ft thick, carrying from 50 to 200 ounces in silver, from 25% to 60% in lead, and containing but very little waste rock mixed in it. The present product is 50 tons daily.

MINING NOTES.—Cinema Journal, June 21: On the Cumison & San Juan a gold lead was discovered a few days ago, carrying free gold from rock down three ft. The rock assays \$3,400. The Gold Fleeces, located at Playame gulch, two miles from Animas forks, produced surface ore assaying as follows: Gold, 8,061 ounces; coin value, \$101,420; silver, 5,698 ounces; coin value, \$2,263.76; total, \$103,683.76. From 300 pounds of second-class ore, was obtained, by mill run: Gold, 10 ounces; silver 53 ounces. From 1,831 pounds third-class ore, was obtained:

The Australian Bustard.

The very interesting specimen of the feathered tribe which adorns our first page this week, is known as the Australian bustard (*Otis Australasianus*), and is the largest and handsomest of that family of birds.

The bustard inhabits the grassy plains of Europe, Asia and Africa, none being found upon our own continent. They vary in size according to species, the great bustard weighing from 25 to 30 pounds.

According to Gould, the Australian bustard exceeds in size the European, standing higher upon its legs and having a longer neck. When seen at freedom no Australian bird, save the emu, is so majestic or assumes in its carriage so great an air of independence. The male, whose weight is from 13 to 16 pounds, greatly exceeds

graving, is the long pouch which adorns its breast, and which, when inflated, reaches almost to the ground. This development is said to be peculiar to the breeding season, and is connected with the vocal organs, which, at that time, are much exercised.

THE MANUFACTURE OF PHOSPHORUS.—Various mineral phosphates, said Mr. James Readman, before the Glasgow Philosophical Society, are now used in the manufacture of phosphorus. Bone ash is no longer remunerative, on account of its high price. Among the varieties of mining phosphates are Canadian, German or Nassau, Charleston and Sombrero phosphates. The first stage in the manufacture of phosphorus is to decompose the phosphate of lime completely in a large cylinder with sulphuric acid of 110° to 120° Twaddell, with constant agitation. The sulphate of lime is then filtered off, and the filtrate is evaporated to about 80° to 90° T., and

Arizona Mines.

The Silver King mine, situated in the northern part of Pinal county, Pioneer district, in a basin at the foot of a steep mountain range, was discovered in 1875 by C. G. Mason, B. W. Reagan, W. L. Long and Ike Koplin, and was the first location placed on record in Pinal county. The vein matter is quartz, the minerals consisting chiefly of chloride and black sulphurets, with quantities of pure silver in nuggets. The old shaft is down 257 feet, and drifts and tunnels in all directions show that the mineral is not only deposited on top of the ground, but extends down into mother earth. A new working shaft has also been commenced which is to be sunk 1,000 feet. There is now in sight, by actual miners' measurement, \$1,000,000 besides \$750,000 worth of ore on the dump and tailings at the mill, which latter are to be reduced by

go and prospect there. They were strongly advised by their friends not to go on what they considered a fool's errand, and told them they would find their tombstones there and nothing else. "All right," replied the boys, "tombstones let it be, if we can't do better, but we will chance it." And away they went, up amongst the wild hills where the attack of the treacherous Apache was no less probable than the miners' every-day risk of accident and starvation. But none of these mishaps befel the brave lads; they were singularly fortunate in lighting upon a magnificent vein of silver ore, which piece of good luck was followed by the discovery of other veins equally valuable, in the same neighborhood. A mining camp was immediately organized by the discoverers, who, in derision of the dismal forebodings of their friends, gave it the doleful name of the "Tombstone" district.

Silver mountain, just south of the Bradshaw range, is attracting considerable attention; in fact, all the leads of gold and silver that stand

THE AUSTRALIAN BUSTARD OR NATIVE TURKEY OF AUSTRALIA—*Otis Australasianus*.

the female in size, and from the greater length of the plumes of the neck is much more stately in appearance.

The bustard is so shy and runs with such marvelous rapidity when once alarmed, that great care is required hunting them. To succeed in getting near, it is necessary to bring in the aid of a horse, and to approach in circles, gradually closing in upon it before it takes wing, which it readily does by running a few yards, thereby gaining an impetus, which enables it to rise. It flies heavily, with its long neck stretched out to the utmost, but it is capable of sustaining flight for a considerable distance.

As an article of food it is said to be delicate and well flavored, surpassing the turkey of the European country. It breeds in the latter part of September, the situation chosen for the purpose being a clear spot in some valley or on the side of a grassy hill. The eggs are usually deposited on the bare ground; occasionally a few sticks are spread for them to lie upon.

A very striking peculiarity that will be noticed about the larger bird (the male) in the en-

then allowed to cool. It contains over 25% of phosphoric acid. It is then mixed with coarse wood charcoal and dried in a muffle furnace. The proportion of charcoal to liquor is one to five. This substance contains the phosphoric acid in a partially insoluble state, so that it is different in its properties from meta-phosphoric acid. The mixture is then transferred to retorts of Stourbridge clay, capable of holding 30 to 40 pounds. The malleable iron pipe through which the phosphorus distills is then luted on, and the heat is raised to bright redness. The phosphorus distills over and is condensed in water. It only remains to cast it in molds, when it is sent to market. Mr. Readman, in contradiction to usual assertions in text books, called especial attention to the fact that mono-phosphate of lime is not used as a source of phosphorus, for the lime takes up valuable room, and the compound requires a much more intense heat to effect its decomposition. Redonda phosphate of aluminum is regarded by the author as the future source of phosphorus, but as yet no attempt to procure phosphorus from it has been pecuniarily successful.—*Iron Age*.

amalgamation, a process the company is about to introduce to their otherwise perfect mill, and thereby save that which is lost by present process. The entire cost of the mill was \$60,000. Wood and water are in the vicinity of mine and mill, and the property is distant from terminus of the Southern Pacific railroad but 60 miles. The ore is hauled from the mine to the mill, four miles, in wagons. About 50 men are employed by the company. Picket Post and the town of Silver King both show considerable activity.

The ill-omened title borne by the Tombstone district indicates the ready wit of the hardy miners in coining names for new places, and also the pertinacity with which a name will stick to a man or place when it has once taken popular hold. The story as to the origin of the name given to the district is, that two young miners, brothers, named Schœln, had reached Tucson in the early part of last year, on a prospecting journey. While there they heard of some likely indications that had been seen on the hills around the San Pedro river, about 70 miles away from Tucson, and made up their minds to

out so prominently in the Peck, Bradshaw and Tiger districts seem to tend toward Silver mountain as their objective point, and to culminate, as it were, in a grand fountain head, a monster ledge which has its home in Silver mountain. This ledge has been named the Mammoth, and is at one point 150 feet between casings, and shows mineral for a distance of three or four miles across the mountain. No work has yet been done on any part of the ledge, so as to determine whether there are rich ore chutes or not, and it will take a large sum of money to prospect it, consequently, it may be some time before the world will know its value.

PHOSPHORESCENCE.—In a certain butcher's shop all the meat became strongly phosphorescent and remained so as long as sound. If putrefaction set in and *Bacterium termo* made its appearance the luminous appearance ceased. None of the customers of the meat experienced any inconvenience from its use, and no similar phenomenon was traced in other butcher's shops in the neighborhood.—*M. Nueesch*.

THE ENGINEER.

River Taming in England.

The English government is now at work on a problem which is engaging attention in this State, and in other parts of the world, viz., the devising of some method by which the surplus water from the mountains may reach the sea without this destructive floodings of the low lands, which now follow the rain storms or snow meltings on the highlands. In England, this flooding of low-lying districts has become more destructive during recent years, because the systematic ditching and underdraining of the uplands give quick passage through the soil into the rivers to the surplus water which formerly was long held on the surface or percolated but slowly through the soil. We find but meager information concerning the provisions of this act which is now before Parliament for the averting of floods, and can do but little more than state the fact without description of methods proposed. It may be said, however, that the subject has been studied by a royal commission and that a scheme has been elaborated from the report of their investigations. The *Agricultural Economist* thinks that the whole project is endangered by the fact that the proposed act orders that a part of the expense of carrying off the water shall be taxed upon the uplands whence the waters come. This, our exchange thinks, will awaken much opposition to the contemplated improvements. We suppose the uplands will hold that as water is prone to run down hill, it is no fault of the hill, but the iniquity is rather in the water, and if those below do not care to suffer injury they must get out of the way, or else corral the water so that its destructive power is held in check. This it is proposed to do by widening these rivers, and the power to carry out these improvements is to be vested in "River Conservancy Boards," who shall have full authority to condemn adjacent property, mill rights and the like, as their plans may require. One recommendation of the report is, that all arterial streams insufficient to carry their waters after heavy rains be widened very considerably indeed, and that the new banks be formed gradually shelving down to the banks of the stream that they may be available to bear grass either for mowing or for feeding of stock, when the waters are low. If this were carried out, the conservancy boards would no doubt let these river banks by the season, the revenue derived from which would lighten the taxation for the conservancy rats. Although most of the rivers would require considerable widening, this shelving bank system might, in a great measure, prevent the waste of land which would take place if conducted on any other principle.

In addition to preserving the lowlands, it seems that the system of upland reservoirs, for irrigating low land meadows, is also contemplated, and this the *Economist* regards as a very promising feature. This has also been proposed for our own turbulent rivers. It is interesting to note the testimony brought forward in England in favor of irrigation, and comparing their moist climates with our arid one, we can but say if irrigation will do these things in the green tree, what will it do in the dry. Our exchange says that if "there is one thing we are behind in more than another in our British husbandry, it is in making that extensive use of water which is made on the continent and in the East by processes of irrigation." It then proceeds to read English feed growers the following lesson: "The recommendations of old Arthur Young for laying out fresh water meadows might still be studied to advantage by the owners and occupiers of numerous districts, and as to benefits derivable therefrom, the same writer records an instance where nearly five pounds an acre was realized for the feed of a water meadow during six weeks of spring, and that nearly two tons per acre of hay was reaped from the land afterwards the same summer, which, together with the after-grass in autumn, made a splendid return. Yet when the same meadow could not be irrigated owing to some disputes respecting the water rights, very little whatever was grown on it."

These propositions to curb rivers from their wild work and harness them forever in the service of the farm, is one of the most interesting and important which is now advanced for agricultural engineers to reduce to practical operation.

GOLD IN RUSSIA.—The St. Petersburg papers report a great development of the gold production in Russia. Strata containing gold dust in considerable quantity have recently been discovered in the Ural mountains. It is said that in the district of Sennigai a Russian proprietor has found in his gold mine, near Motygin, a nugget 445 pounds in weight, representing a value of nearly \$75,000.

SIXTY-THREE years of age is said to be the grand climacteric or turn of life, a critical period for masculine humanity, more men dying at that age, or near it, than at any other, leaving accidents and violent deaths aside. A like critical period for feminine humanity is 47 years.

USEFUL INFORMATION.

ASPHALT AND TIMBER FLOORS.—A new method of laying down floors has been adopted in France, and is said to have obtained a wide application. It consists in putting down a floor, not as hitherto, on joists, but in embedding the boarding in asphalt. The new floors are used mostly for ground stories of barracks and hospitals, as well as for churches and courts of law. Pieces of oak, usually 2½ to 4 inches broad, 12 to 30 inches long, and one inch thick, are pressed down into a layer of hot asphalt not quite half an inch thick, in the well-known herring-bone pattern. To insure a complete adhesion of the wood to the asphalt, and obtain the smallest possible joints, the edges of the pieces of wood are planed down, bevelling toward the bottom, so that their cross section becomes wedge-like. Nails of course are not necessary, and a perfectly level surface may be given to the flooring by planing after the laying down is completed. The advantages of this flooring, which only requires an even bed upon which to rest, are said to be the following: 1st. Damp from below and its consequences, rot, are prevented. 2d. Floors may be cleaned quickly and with the least amount of water, insuring rapid drying. 3d. Vermin cannot accumulate in the joints. 4th. Unhealthy exhalations from the soil cannot penetrate into living rooms; asphalt being impermeable to damp, rooms become perfectly healthy, even if they are not vaulted underneath. In buildings consisting of several stories, as in hospitals, the vitiated air of the lower rooms cannot ascend, an object which it has hitherto been impossible to attain by any other means. 5th. The layer of asphalt will also prevent the spreading of fire from one floor to another in case of conflagration.

HEPTANE.—Six or seven years ago abietene, a hydrocarbon obtained by distilling the exudation of the nut pins or digger's pins of California (*Pinus sabiana*), was introduced in market and sold in a crude state under various names, and is now used for removing grease spots, etc. It is aromatic, colorless and very liquid. Chemists lately made a pretty thorough chemical and physical examination of this abietene, and found it to consist mainly of pure heptane—a substance the other known natural sources of which are petroleum and fossil fish oil. The occurrence of a paraffine playing this part of oil of turpentine in a tree now living is exceedingly interesting. In ordinary turpentines a paraffine-like substance has been found, but only in very small quantities. The composition of the oil of the *Pinus sabiana* probably varies at different seasons, as sometimes the nuts taste strongly of turpentine, and at other times they have hardly any of that flavor.

SEA WEEDS FOR THE HERBARIUM.—The recipe for pressing sea weeds for preservation used by the Rev. A. B. Hervey, of Troy, N. Y., well known as an expert in that process, is as follows: Float out each specimen by itself in salt water, in a white dish, like a washbowl. Put the paper under the plant in the water; arrange the plant on the paper and carefully draw it out. Lay the paper with the plant upon it on drying paper and spread over it a piece of white muslin. Then spread over this a layer of drying paper, then more plants, and then more cloth, drying paper, etc. Put all under a board, and weight it with 40 or 50 pounds of stone or other heavy substances. The next day change the cloths and drying paper, and in one day more the plants will be dry and ready to go into the herbarium or the album for permanent preservation.

IMITATION INLAYING.—Suppose I want an oak panel with a design inlaid with walnut. I grain the panel wholly in oil. This is not a bad ground for walnut. When the oak is dry, I grain the whole of the panel in distemper. I have a paper with the design drawn thereon, the back of which I rub with whiting, place it on the panel, and with a pointed stick trace the design. I then with a brush and quick varnish trace the whole of the design. When the varnish is dry, with a sponge and water I remove the distemper, where the varnish has not touched. This, if well executed, presents a most beautiful imitation of inlaid wood. Marbles are executed in a similar manner.

BABBITT ANTI-FRICTION METAL.—The metal is made of one part copper, three parts tin, two parts antimony, and three parts mors tin are added after this composition is in the molten state. This composition is called hardening, and when the metal is used for filling boxes, two parts tin are used to one of hardening. The above alloy constitutes the best anti-friction metal in use, but on account of its expense it is very little used. The anti-friction metals commonly used are principally composed of lead, antimony, and a little tin, but they are not nearly so good as the above.

PASTE TO MAKE PAPER ADHERE TO TIN.—Soften 4 parts of glue in 15 of cold water, and then moderately heat until the solution becomes quite clear. Then add 65 parts of boiling water, and agitate. In another vessel stir up 30 parts of starch paste with water enough to form a milky liquid without lumps, and into this pour the boiling glue solution with constant stirring. Continue the boiling for a few minutes, and add, after cooling somewhat, a drop or two of carbolic acid to each gallon of paste. Keep the paste in closed vessels.

TO TEMPER DRILLS, GRAVERS, ETC.—Select none but the finest and best steel for your drills. In making them, never heat higher than a cherry red, and always hammer till nearly cold. Do all your hammering in one way, for if, after you have flattened your piece out, you attempt to hammer it back to a square or a round, you spoil it. When your drill is in proper shape, heat it to a cherry red, and thrust it into a piece of resin or into quicksilver. Some use a solution of cyanuret potassa and rain-water for tempering their drills, but for my part, I have always found the resin or quicksilver to work best. Gravers and other instruments larger than drills may be tempered in quicksilver as above; or you may use lead instead of quicksilver. Cut down into the lead, say half an inch; then, having heated your instrument to a light cherry red, press it firmly into the cut. The lead will melt around it, and an excellent temper will be imparted.

HOW TO MAKE COURT PLASTER.—Soak isinglass in a little warm water for 24 hours, then evaporate nearly all the water by gentle heat, dissolve the residue in a little proof spirits wine, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cool. Now stretch a piece of silk or sarsenet on a wooden frame, and fix it tight with tacks or pack-thread. Melt the jelly and apply it to the silk thinly and evenly with a badger hair brush. A second coating must be applied when the first has dried. When both are dry, apply over the whole surface two or three coatings of balsam of Peru. Plaster thus made is said to be very pliable and never breaks.

EMERY BELTS AND WHEELS.—A correspondent says that most users of emery belts and emery wheels do not use glue that is thick enough, fearing it may chill before the sand or emery can be spread. In making an emery wheel or belt, if the cloth has never been glued, it should be sized with glue about as thick as lard-oil, and allowed to dry thoroughly before applying the glue which holds the emery. Have the emery heated to 200° Fah., and coat the belt or wheel with glue about as thick as molasses and roll it in the hot emery. If a wheel or belt thus treated is allowed sufficient time to become thoroughly dry, it will be very serviceable.

HOW TO MAKE PLASTER OF PARIS HARD ENOUGH FOR TURNING.—Mix with fresh plaster of Paris from two to four percent. of powdered marsh mallow root, then add sufficient water until it forms a mass. This will set in about an hour and become so hard and dry that it may be sawed and turned. It is used in the manufacture of dominoes, dice, etc. When eight percent. of the root is added a still harder mass is obtained which may be rolled into leaves and painted or varnished. A small quantity of alum added makes it set harder and quicker.

PURITY OF MILK.—It is stated in a German paper, that the purity of milk may be tested by the following very simple method: A well-polished knitting needle is dipped into a deep vessel of milk, and immediately withdrawn in an upright position; when, if the sample be pure, some of the fluid will be found to adhere to it, while such is not the case if water has been added to the milk, even in the smallest proportions.

GOOD HEALTH.

Hyposulphite of Soda in Erysipelas.

Anthony's Bulletin contains the following concerning the hyposulphite of soda as a remedy for erysipelas: "When erysipelas proceeds from a wound, it is more delicate to manage, and requires the best surgical skill; but when it is of the milder form, on the outside skin in the face or any other part of the body, proceed as follows: Take of hyposulphite of soda any quantity, and make a saturated solution in a bottle of any convenient size—six, eight, or ten ounces. If the individual is a strong, hearty man, and the disease has a good start, give your patient one tablespoonful every hour for twelve hours; then decrease the dose, as the benefits become manifest, say once in three hours. It may cause diarrhea; but never mind, it will destroy any febrile symptoms. Twenty-four hours is generally sufficient to produce a decided change for the better, unless it has six or seven days' start, in which case it will take longer. The results are generally so wonderful that I have never known the remedy to fail." With an old person you may substitute a teaspoonful for tablespoonful, and once every two hours. You may put this down: that the sooner you can get a good quality of the soda solution into the body, the sooner the troubles will be over. Now, for an outward application: use equal parts of the soda solution and glycerine; saturate cotton flannel with the above, and lay on the part affected. Eat simple food—avoid all exciting food and drink; farinaceous diet is absolutely necessary. If you can bathe the part affected with the above solution, do so; then lay on the saturated cotton.

"Hypo" is equally as efficacious in any poisons from insects or vegetables; old wounds in sores are healed by washing the parts in a solution of

soda. It is also good in typhoid fever, carefully administered.

"Now, if a person has a form of erysipelas that is not so decided, but (say) chronic, let him take a teaspoonful every night of the solution, and the disease will be entirely removed, if kept up for a month. The disease seldom or never attacks a person the second time when eradicated by the soda treatment."

Food and Digestion.

In a lecture before the Workingmen's Lyceum, Dr. Seguin spoke as follows of food: "An ordinary meal is generally composed of five ingredients—animal or nitrogenous food, starchy or sweet food, watery vegetables, beverages and condiments. This food when digested is taken into the system by blood vessels. For persons, and especially for workingmen, in this climate, meats are the most easily digested, and at the same time are the most nourishing food. Tripe is the easiest and pork the hardest to digest. Among vegetables, rice and boiled cabbage are the extremes. Anything that is hoiled in fat is extremely indigestible. Milk contains the five ingredients referred to above, and so is really 'all-sufficient.' Mothers make a great mistake in trying to induce infants under two years of age to eat starchy food, for there is no alkaline fluid in the stomach of an infant by which the starch can be changed to sugar, and so infused into the system. It has been estimated that a man working in the open air daily needs 15 ounces of meat, 18 ounces of bread, ¾ of butter or fat, and 51 of water. I agree with many eminent chemists who have proved that alcoholic drinks are an aid to the system in retarding the waste of tissues. So, too, for the same reason, I regard tea and coffee as nourishing. An excess of starchy food is to be carefully avoided. Men who handle lead ought to abstain from alcohol, for if too much is taken the kidneys, which throw off the poison of this lead, are likely to become diseased."

Nature has supplied an infinite variety of food to suit every taste and the gratifications of every stomach. "What is one man's meat is another man's poison," is an old and true saying. The whole of good health may be concentrated in the simple observation to "eat only what agrees with you." Volumes of information can give no better or other advice. No physician can prescribe a more efficacious remedy.

CHILD MURDER.—The hutchery of the Freshman child at Pocasset strikes everyone with horror. Yet the brutal father accomplished directly what is being accomplished indirectly and unintentionally, in many instances, by parents who either neglect their children or remain in willful ignorance of the ordinary and proper laws of health. The command to increase and multiply meant something else than the mere bringing of children into this world to assassinate them by degrees after they are hers. While pouring out oceans of blood and volumes of words to maintain the rights of full-grown men and women, the making of men and women in the proper mind and body, by the proper training of children is overlooked in a great measure. And any religious zeal which prescribes a sickly diet for mind and body and restrains the exuberance of childhood by too great a solemnity, is murder not so speedy, to be sure, but fully as wicked as the Pocasset tragedy.

THE TEETH.—As the result of numerous trials made by the exposure of recently-extracted teeth to the exposure of various substances, M. Maurel comes to the conclusion that if various medicinal substances are injurious in their action on the teeth, others in still larger numbers prove, in their habitual employment, quite inoffensive. Thus, if we are required to take great precautions respecting citric acid, tannin, chlorides of zinc and antimony, perchlorides of iron, sulphate of copper and alum, we may continue to employ with complete safety arsenious and carbolic acids, vinegar, corrosive sublimate, chloride of potash, alcohol, tincture of benzoin, essence of mint, tincture of quinine and eau de cologne. Tobacco, whether used in chewing or smoking, does not injure the teeth beyond their discoloration.

DISEASE GERMS.—C. Von Nagell, a Bavarian investigator, while he retains the idea that the smallest organisms, fungi, are the cause of all infectious diseases, holds that only these germs are dangerous and calculated to infect which enter our organs of respiration with the air we breathe. If Von Nagell's theory should prove true, and find general acceptance, it would be no longer necessary to trouble ourselves about the generation of products of decay in masses of liquid, as in sewers, canals, damp soil, river and spring waters. On the other side every means must be employed to prevent these fungi diffusing through the air as a result of the drying up of such decaying masses.

PROPERTIES OF GLYCERINE.—Glycerine should not be rubbed on the skin in an undiluted state. One of its remarkable properties is its power to absorb moisture, and hence its irritating effect on the skin. About three fluid ounces of water to one of glycerine will form a mixture which will neither attract moisture nor evaporate, the weight scarcely varying from week to week, either in one direction or the other. The mixture should be kept in a cool, moist place and used as required.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Earthquakes—No. 2; Mechanical Interests of the Coast, 1. The Week; In Memoriam; Darien Canal; Our New Volume; The Extrinsic Burdens of Mining, 3. Copper Mines of Japan; A New Property of Circles; Water Rights; Centrifugal Pumps for Irrigating and Reclaiming Lands; The Sutor Tunnel; Australian Exhibition; Fire in the Mines; Meteorological Summary for June, 9. Notices of Recent Patents; Geological Section, 12.

ILLUSTRATIONS.—Diagram Illustrating Reflection of Earthquake Waves, 1. The Australian Bustard or Native Turkey of Australia, 6. Centrifugal Pump for Reclaiming land, 9.

CORRESPONDENCE.—Shasta County; Chrome Mines in San Luis Obispo; Great Western Quicksilver Mine, 2.

MECHANICAL PROGRESS.—Cable Towing; Electric Car Signal; Apparatus for Feeding Boilers; Gas Engines; The Latest Telephone; European Stoves; Wire-Bound Sheaves and the Millers; Car Heater; Working Steam at High Pressure; Steel-Faced Iron Plates; Soft Steel being used for Tin Plates, 3.

SCIENTIFIC PROGRESS.—Centrifugal Force and Fly Wheels; Underground Telegraphing; Prehistoric Remains in Oregon; Location of the Garden of Eden; Fuel-Gas from Water; Telephones Without Diaphragms; The Heliograph; New Use for Paper, 3.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 4.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico and Oregon, 5-12.

MISCELLANEOUS.—The Telluride Ores of Gold; The Treatment of Auriferous and Argentiferous Pyrites, 2. The Australian Bustard; The Manufacture of Phosphorus; Arizona Mines, 6.

TECHNICAL.—River Taming in England, 7.

USEFUL INFORMATION.—Asphalt and Rubber Floors; Heptane; Sea Weeds for the Herbarium; Imitation Inlaying; Babbitt Anti-Friction Metal; Paste to Make Paper Adhere to Tin; To Temper Drills, Gravers, Etc.; How to Make Court-Plaster; Emery Belts and Wheels; How to Make Plaster of Paris Hard Enough for Turning; Purity of Milk, 7.

GOOD HEALTH.—Hypophosphite of Soda in Erysipelas; Food and Digestion; Child Murder; The Teeth; Disease Germs; Properties of Glycerine, 7.

NEWS IN BRIEF on page 12 and other pages.

Business Announcements.

American Machine and Model Works, I. A. Heald, Prop'r Butts' Improved Fruit, Vegetable, and Hop Drier, Berkeley Property For Sale, S. A. Penwell, S. F. Threshing Outfits, Jackson Agricultural Works, S. F.

The Week.

The most noteworthy event of the week in the mining world is the final completion of the Sutor tunnel, consummated after an almost uninterrupted prosecution of the work for nearly ten years. Some finishing up remains to be done on the great adit, but in its readiness to receive and handle all the water from the Comstock lode it accomplishes the main object of its construction and relieves the mine owners from a service that had already become troublesome and costly. They are now in a position to go on and prove the lode in depth, and make their ores profitably available if they exist in sufficient quantity and reach even a medium grade. As the Tunnel company are dependent on the resources of the mines for revenue, it is as much to their interest as it is to that of the mine owners themselves that valuable ore bodies should now be developed, wherever it may be expected that these parties will now bury the hatchet and hereafter work harmoniously together. The weather in the interior continues favorable to mining operations, the snow lingering on the mountains and keeping the hydraulic claims well supplied with water. Bullion receipts during the past week have been fair, shipments from the hydraulic mines having been liberal and from all parts of California fully up to the average at this season of the year.

MEXICAN COMMERCE.—The actual annual commerce of Mexico with other nations, according to the latest official data, is as follows: Imports, \$29,500,000; exports, including \$22,000,000 of precious metals, \$28,750,000; total, \$53,250,000. Compared with the population the total equals \$5.82 for each inhabitant, while the United States equals \$27 per head, Cuba \$120 per head, Spain \$17 per head.—*El cinco de Mayo*.

In Memoriam.

Bereavement presses heavily upon us. At her home in this city, on Sunday morning, died Hosapher N., wife of Warren B. Ewer, senior editor of our publications. She has suffered long and patiently, hoping against hope, that the malady which had fastened upon her would loosen its grasp and restore her again to her beloved ones, to her wide circle of friends—again to the life of kind thoughts and gentle deeds in which she delighted. But the God in whom she trusted willed otherwise. On Sunday morning, fatigued with pain of unusual severity with which she had battled, she fell asleep, and while her devoted husband and attendants rejoiced to think the quiet slumber would refresh her, she peacefully crossed the river. Her loss is bereavement beyond words to those of her immediate household, and in the larger circle, in which her presence was a ray of sunshine and an influence toward purity of thought and nobility of conduct, the tributes to her memory are tender and heartfelt.

Mrs. Ewer was born in 1817 in Havana, Cuba. In youth she removed to the old commonwealth of Massachusetts, and there she and her future husband began an acquaintance as playmates which ripened into mutual affection. During seven years of plighted troth they awaited their marriage, and since then 40 years of union have cemented their lives together. During their early married life she was an invalid for many years, and the sympathy quickened by this experience knit them the closer. Mr. Ewer came to California in 1849, and his wife followed him four years after. They resided in Grass Valley about 8 years, making many friends. For 17 years they have lived in San Francisco. Four children were born to them, one dying in the full vigor and promise of early manhood; another, a devoted daughter, still survives her mother. This daughter and an elder sister, both in delicate health, Mrs. Ewer leaves in charge of her bereaved companion.

The life of Mrs. Ewer was one of nobility, and her heart was full of generous impulses. In deeds of charity she was constant. Her work lay in those quiet actions in behalf of the suffering and the unfortunate, of which the world never knows, as well as in organized efforts for wider charities. She was one of the lady members of the Board of Managers of the "Sailor's Home" in this city. This project was very dear to her, and while her strength lasted she gave it generous and self-denying promotion. As a member of the Union Square Baptist Church of this city, she lived a consistent Christian life and was earnest in every good work. Frankness in words, firmness and decision in character, with unswerving devotion for the right and kindness toward all in the least deserving—these were strong characteristics of her life.

Mrs. Ewer possessed what may be truly called a sunny disposition. In her friendships she was most honest and outspoken, and one of the results of her illness, which she most deplored, was her separation from her friends. Her conversation was full of the charm of animation, and while it disclosed thoughts born of wisdom and research on the themes she preferred, it was always warmed by true womanly sympathy and genuine philanthropy. She was the life of the social gathering, the light of her home, an influence toward the elevation of all who came within the circle of her acquaintance. Thus she will be widely mourned, and the sense of loss, itself the highest tribute to the worth of one departed, will press itself upon many a mind and heart. Though a great sufferer for many months she retained her kindness of disposition amid all her sufferings, and one of her greatest trials was the burden which she placed upon those who loved her—a burden which was lightly borne because of her hold upon the hearts of those who ministered to her.

She has gone hence. During her lifetime her trust was full and her faith serene, and to such souls to die is gain. Not to her, but to those whom she has left behind are honest words of sympathy fitting. To our associate, to whom for 40 years she was a loving wife and true companion, we extend the most heartfelt assurances that we grieve with him in his bereavement, because we know how much a part of his life her presence and companionship had become. He and his daughter are heretofore and alone—and yet not alone, for love and memory do not die. Theirs it is to cherish a memory which will always come to them, sweeter far than fra-

grance of flowers; more precious than anything of earth can be, for their treasure is now beyond the pain and suffering of earth, in glad possession of the peace beyond.

The funeral of Mrs. Ewer took place on Tuesday afternoon, July 1st. Both at the home and at the church there were throngs of sympathetic mourning friends. Floral offerings were many. At the church there was a large cross, flower-set, encircled by a wreath of flowers. There was also an anchor of woven blooms. These were regarded by all as fitting emblems of her devotion and faith. An eloquent sermon was preached by Rev. Mr. Ross, pastor of the church and a touching tribute to the Christian virtues and noble life of the deceased by Rev. Mr. Hughes, pastor of the Baptist church at the Mission. Both in the public exercises and in the tender words spoken at the home were to be found eloquent testimony to the worth of her they mourned, and assure us that she still lives in the hearts of the community.

Darien Canal.

We shall have occasion to present to our readers in a short time a complete exposition of the proposed canal. In the meantime the resolution offered in the last Congress by Senator Burnside with reference to the foreign ownership of the Darien canal interfering with the Monroe doctrine, has been criticised by the press of France in such a manner as can leave no doubt that Senator Burnside's ideas were correct. It appears from *La Republique Francaise* that the canal will be absolutely neutral territory, and that in consequence America need not fear entrusting the management thereof to foreign hands. This absolutism is just what America has always and will always contend against. Its destruction was the reason of the Monroe doctrine, and the true doctrine of national free will finds an ardent exponent in the American nation. Hampered on every side by the restrictive ties and contracts with nations foreign to this continent, how can this country hope to maintain its prestige? This Darien canal question comes home to our interests, if not more, as much, at least, as our war with England. What the nation cannot accomplish by brute force, they are now attempting to accomplish by diplomatic skill and finesse. "The United States must be checked." It has penetrated to every quarter of the globe with its mechanical and industrial products, and is fast crowding out of the markets of the world the products that heretofore have given European nations their greatness. We cannot afford to permit this thing, and on our own coast the matter is of great importance. The Orient is open to us, and we are gradually commanding its trade. Europe cut off by the natural obstruction of the Western continent, seeks by every effort to cut us off. National ambition to grasp the commerce of the East is the mainpring that moves northwest passage expeditions, and years ago the Darien canal was broached but suspended because it was thought a passage through the Polar sea would be discovered and made available. But now there is no hope of a highway in that direction, so the Darien canal has assumed its complete features. Upon the assumption that the United States can control eventually the commerce of the world, the foreign element on this hemisphere must be kept at a distance, and to Americans belong the right of controlling a highway theirs naturally. The same policy that European nations adopt to protect their commerce, must be adopted and enforced by us; and there is not a nation on the earth that would oppose us in our demands, or that would resist our enforcement of the Monroe doctrine. The star of Europe is setting, while our star of empire is ascending, hence the struggle of Europe to renew its luster at the expense of ours.

Our New Volume.

The MINING AND SCIENTIFIC PRESS, with this, the first number of Vol. XXXIX., enters upon its twentieth year. They have been years of hopes and fears. Our fears generally have proved groundless, and we are glad to say that we have witnessed a growth and progress unparalleled in the history of States. True, population has not increased in proportion to wealth, but on that account our progress has been solid. We believe our efforts to satisfy the demands for a mining and scientific journal have been and will continue to be appreciated, and we shall not spare any efforts to justify a continued and additional patronage. The period of dullness through which we have been passing is not due to local causes, but the business of the whole world has been and still is affected by what may be termed a "business epidemic," the causes of which cannot with certainty be ascertained. The clouds, however, are breaking, and we are sure that the new volume will be able to record a period of unparalleled prosperity, which our mining interests will permit us at present to expect.

The Extrinsic Burdens of Mining.

It argues well for the solid merit of gold and silver mining on this coast that it has been able to stand up and even flourish under the extravagance, fraud and other forms of abuse that, almost from its inception, have characterized the business. Hardly more than a year had elapsed after the discovery of gold in California when the miners, crazed with cupidity and impelled by the wildest vagaries concerning the origin of that metal, its modes of distribution and most apt places of lodgment, were betrayed into every manner of folly in the adoption of means for more speedily gathering it. Even so early as the summer of '49, when the miner with his shovel and rocker could almost anywhere wash out his ounce per day, with fair chance for making a good deal more, multitudes were ready to forego this sure thing and engage in any absurd scheme that promised to insure them larger returns. At that primitive day these men were ready on the slightest hint of rich discoveries elsewhere to abandon their claims and scamper off for the site of the reported find, however vague the rumor or distant the locality.

But, however excitement and follies have attended this calling from the first, not until the era of vein mining was inaugurated did these evils take on those novel and more mischievous forms that have since distinguished that branch of the business. If the early placer miner, misled by false rumors of big things far away, hurried off to remote points only to meet with disappointment and loss, his premature movements wrought harm to himself and no one besides. If, incited by greed, he engaged in ill-advised and ruinous experiments, or embarked his means in visionary schemes, he alone was the sufferer. Very different has it been in this other department of the business. Here, the consequences of the miner's mistakes and the manipulator's misdeeds have not been confined to this narrow scope. They have afflicted all classes, and fallen mainly on those nowise in fault. Here innocent parties have generally been the greatest sufferers. With the advent of this branch of mining came new ideas and new modes of procedure. With its growth there sprang up institutions and practices not in use before. Then, for the first time, incorporated companies, with numerous well-paid officials, luxurious quarters, large amounts of fictitious capital, and their cunning machinery for assessing shareholders, freezing out delinquents and favoring insiders, became common. Then the Stock Exchange, with its accessories, arose stately and potent, an instrument of some good and infinite mischief. Then the broker—the Bull and the Bear—came upon the stage, and corners and pools, puts and calls, and other methods of operating, with much besides of uncouth sound and unsavory morality, first began to be heard of. What has since followed may be inferred from the accumulated wealth of the few and the abject poverty of the many who have much dealt in mining stocks, somewhat also being of record in our bankrupt commissions and criminal courts.

We have alluded to these illegitimate burdens that so oppress mining, not with the purpose of now inveighing against them, but merely to show how inherently sound must be the business that can stand up and prosper under so great a weight. Under so many hindrances no other industry could have made such progress, or even survived for any length of time. It is, in fact, to the great opportunities afforded by mining that these rank abuses have been mainly due. It was because the business could bear them without being fatally crushed that they have been so often perpetrated and so persistently kept up. But a time has come when some check should be put upon these damaging practices, both for the good of the business itself, and the cause of public morality. It is time the taxes should be weeded from the wheat, to the end that our bullion harvest suffer not early curtailment. Retrenchment and close figuring is the order of the day. The practice of economy is everywhere becoming a vital necessity. The whole business world is pervaded with the sense of saving. Only here on the Pacific coast does it seem to be absent. Presuming on our position and other natural advantages we are spending and wasting, speculating and gambling as before. This we will have to change. Thus far we have had the field mostly to ourselves. We have been able to largely monopolize the business of mining, with all that pertains to it. But we are going to have competitors. They are already in the field—active, sharp, and accustomed to go for all the chances in sight. In contending with them for commercial supremacy we will need to practice the same caution, vigilance and economy observed by our opponents, and to which they have long been schooled. If we think we can pursue this industry in the old reckless and spendthrift way, and still make advances, or even hold our own, we will soon find ourselves grievously disappointed. We will have to fall into line and keep step with the advancing army of close workers and savers if we are to get on and make money at this business of mining.

AFTER two months' debate the Italian Chamber of Deputies has approved the Ministerial Railway bill, which provides for the construction of 6,020 kilometers of railways within 21 years, at the annual expenditure of £2,400,000.

Copper Mines of Japan.

We translate from the *Moniteur Belge* the following account of copper mines and mining of Japan: While Japan is peculiarly remarkable for her mineral wealth of every variety, her principal source of mine wealth is in the abundance and purity of the copper deposits. Copper is in common use in Japan and is either used pure or alloyed for a great variety of purposes. Every mineral known to Europe is found in Japan, but the most universal is copper pyrites or sulphuret, malachite, azurite and even native copper in beautiful crystals are found in considerable quantities, but the sulphuret alone is utilized in the manufacture of the metal.

The deposits are very numerous, the pyrite is generally enveloped in a soft, decomposed quartzose gangue if the deposit be ancient, but very hard in recent formations. The product is frequently both auriferous and argentiferous, but the precious metals are never extracted except in the government mines. The principal rock is a porphyritic feldspar in an older clay, sometimes this porphyritic feldspar is replaced by felsite. The veins are frequent in the porphyry and its transformations and continue without interruption into and through the neighboring rock. The veins of the district of Aui are very numerous; either east or west, carrying copper and poor in lead. Second, veins dipping north or south, containing less copper but more lead than the east and west veins. The width of the lead varies from two inches to four feet. The wall is composed of quartz, fragments of clay, pyrites, galeua, blende, etc. The production of these mines during the eight months of the last annual report reached 512,532 pounds. The leads running east and west are richer in minerals than those running in any other direction.

The same peculiarity is apparent in the greater part of the mines of Japan. While other nations in locating ledges and veins proceed upon scientific principles, observing the character of the geological formation, the exterior of the mountains, etc., the Japanese go it blind, so to speak. A locality is selected without any regard to formation or condition, and a horizontal gallery is constructed, the entrance to which is sufficiently elevated to provide for dumping. The gallery is continued *ad infinitum*, until an ore vein is found, or the work is stopped by some accidental caving in or geological obstruction, in which case hazard is consulted in constructing another gallery. This gallery is from three to four feet in height and about 16 inches wide, hardly room enough for a small man to pass. Generally timber is useless, but sometimes lateral timbers are put in. When the gallery has accidentally encountered a vein it is followed down, the miners following its inclination by means of single poles, hollowed for foot-rests. The water is kept out of the galleries by means of a series of common suction pumps made of bamboo, and arranged at different heights upon platforms to allow for the elevation. The ore is extracted by means of a hammer weighing about two pounds, and a chisel twelve inches long. The method employed is that of mining by reversed galleries. Explosives are not used, although some of the Japanese miners have used powder, but with disastrous effect upon themselves and so the use is abandoned. The ore is brought out by young children in baskets carrying from 50 to 75 pounds. Each carrier is provided with a small pillow to support the weight upon his head, or too he used as a seat. The mine is lighted by means of shells filled with oil, and containing several wicks of junk. These small primitive lamps are placed in rows along the galleries in holes made for the purpose. The oil used is coconut oil.

Ventilation does not exist, in fact the drift does not penetrate very far into the earth before the water overcomes the pumps, when the gallery is abandoned and a new one commenced.

The ore, if decomposed, is broken up in a species of *arastra*, but when hard, is broken up very small by women and girls, who use a light hammer, breaking the ore against a small pointed anvil, after which it is hammered to powder, as nearly as may be. The dust is then placed in baskets and washed in running water. Women also do this work, being compelled to stand in cold water, day after day, up to their knees. However, small pots of warm water are kept near by, into which the poor creatures plunge their limbs to warm them. The washed mineral is then transported to be roasted, and layers of wood and mineral are alternately placed one upon the other until a regular pyramidal-shaped structure is built up—and fire applied. After being roasted the mineral is weighed and placed into a furnace with wood, charcoal and mineral. The whole mass is fused, the workmen stirring it up and rejecting the scoria with a long bent pike pole. The operation commencing at 4 A. M. is completed about 10 o'clock at which time the fires are covered, and the black, brittle mass removed from the furnace and placed into a second furnace for refining. In the fused mass of the second furnace, a pile of water is thrown, and the solidified surface removed; then more water, and another cake of metal is removed, and so on until the furnace is emptied. Each furnace has a capacity of about 250 pounds. The metal obtained by this second fusion is called *arado*, it is extremely malleable and used for a great variety of purposes, its composition is variable, but generally contains 80%

to 90% pure copper. To obtain *nkagane* or pure copper the metal is fused a third time, rejecting the scoria as before. The government of Japan does not interfere with the exportation of copper, but it prohibits the association of foreigners in the working of the mines, no person, not a Japanese, can have any interest in the mines of the kingdom.

The copper obtained by this imperfect process is of a superior quality and is devoted to an infinite variety of uses, particularly in the manufacture of ornaments. There exists only a trace of antimony and arsenic in Japan copper. The splendid qualities of the copper are due to the excellence of the mineral and not to the primitive mode of extraction, as will be perceived. And in spite of the beautiful ornaments made of it, we have nothing to fear from importation, while Japan has everything to gain in the employ of intelligent scientific labor.

A New Property of Circles.

The following property of circles, which, not having found it mentioned in any work on mathematics, I believe to be new, will be of interest to mathematicians and useful for draughtsmen and surveyors.

Suppose a straight line, AB , be divided at

PUMPING BY HORSE-POWER.

any point into two sections; and a circle be drawn through C with its center on the continuation of the line, CB , with a radius equal to the product of these sections divided by their difference. Then this circle has the remarkable property of dividing any two lines drawn from A and B , so any point, P , on the circle, in the same proportion as the point C , divides the line AB . That is to say, $AC:CB::AP:PB$. This may also be expressed in more general terms, thus: If $AC=m$ and $CB=n$, and the radius r be made $=\frac{mn}{m-n}$; then AP is to PB as m is to n .

Draughtsmen will find this law convenient for reducing or enlarging drawings. Suppose we wish to reduce to three-fifths of the original scale. Then AC must be made equal to 5 and $CB=3$ parts of equal and convenient size. The radius of the circle is equal to $\frac{5 \times 3}{5-3} = \frac{15}{2} = 7\frac{1}{2}$ parts. Take any length out of the larger drawing between the points of the

dividers, place one of them at A , the other on that point of the circle where it meets it. Keeping this latter point in place on the circle, move the other point of the dividers from A to B , then the length now included in the dividers is exactly three-fifths of the former length. This circular reduction scale does away with the use of a truler or triangle, which must be constantly employed when a right-angled triangle is the basis of reduction.

Surveyors will find in this law an easy method for laying out railroad curves. The point C corresponds to the beginning of the curve. Place the instrument at A ; sight at any angle, A ; mark the line on the field by two rods sufficiently far apart. The angle at B is calculated easily by the formula:

(Sine of angle B) = (sine of the angle A) (times $\frac{m}{n}$).

Place the instrument at B and set it at the calculated angle. Send the assistant forward in the line of sight until he is in line with the two rods marking the angle A . Then his position marks a point of the required circle.

L. HEYNEMANN, Civil Engineer.

Water Rights.

The Supreme Court of California at the May term, 1879, decided the following case relating to water rights, viz., *Stine Canal Co. vs. Kern Island Irrigating Canal Co.* In August, 1874, the Kern Island Irrigating Canal Co. appropriated a portion of the waters of Kern river, and conducted the same by means of a canal to the Old South Fork, from which it was taken out lower down the stream, and so continued to do up to about the spring of 1878, when the waters were conveyed through the canals of the defendant, without uniting the same with the Old South Fork. All of the water companies which are joined as plaintiffs, except the Goose Lake Canal Co., appropriated portions of the waters of Kern river prior to the appropriation by the Kern Island Canal Co., and consequently their right to the portions of the water by them respectively appropriated is superior to that of the defendant. The right of the defendant is subordinate to that of the plaintiffs, and it is not entitled to divert the waters of the river to such an extent that a sufficient amount thereof will not flow down the river to supply the plaintiffs with their usual quantity. The injunction

Centrifugal Pumps for Irrigating and Reclaiming Purposes.

We illustrate herewith a form of the Heald & Cisco Centrifugal pumps for irrigating purposes and reclaiming marsh land, for which these pumps are specially adapted.

In one device which is found extremely convenient for works of irrigation and drainage, the centrifugal pump is mounted on a carriage with two large wheels and long shaft, which are attached to the portable engine, and which steady the pump, and keep the belt tight and firm. The suction pipe of the pump is attached diagonally, so as to enable it to be readily placed in the water. The foot valve is placed at the bottom of the pipe, and can be placed on the carriage when required to be moved from place to place.

The cut shows an arrangement for working centrifugal pumps by animal power, in countries where fuel is expensive, or skilled labor difficult to obtain. This mode of raising water will be found very simple and efficient; the machinery is easily transported, and can be erected without the assistance of skilled labor, besides being very durable, and not liable to get out of order.

There is also an arrangement for pumping with an improved horizontal engine working a centrifugal pump fixed over a well for irrigation or any other purpose. When the water is more than 28 feet from the surface, the pump can be fixed 25 or 30 feet down the well, and the engine fly-wheel arranged to work over it; or a counter shaft fixed in the top of the well, and the engine fixed at some distance from it. These engines will be found less expensive than stationary engines and boilers, as they only require foundation sufficient to sustain their weight, being entirely self-contained. The motors and pumps to which we have alluded are being introduced to our agriculturists by Parke & Lacy, 414 Market street, San Francisco, from whom further information as to price, etc., can be obtained.

THE SUTRO TUNNEL.—The mere fact of the completion of the Suto tunnel and its successful operation, will not, of course, give the Comstock lode a new lease of life unless ore bodies actually exist in an attainable shape. The fact, however, cannot be overlooked that had it not been for this tunnel the lower levels of the lode would probably have had to be abandoned. Eight hours after the starting of the pumps the water in the long drowned-out mines was lowered 100 feet, and this fact alone demonstrates the practical success of the gigantic undertaking as a means of freeing the mines of water. The labor on the tunnel will not have been expended in vain even if the ore supply should not exceed the amount invested with reasonable interest. To capital and an energy which we would like to characterize as rugged obstinacy on the part of Mr. Suto, the success of this the greatest tunnel in the world is due. In spite of scientific incredulity and local jealousies, the work went on quietly and resistlessly, and we believe that no one now would feel disposed to have the work undone. The fruits of energy combined with labor show for themselves; failure alone can be attributed to stupidity either on the part of the engineer or the opposing elements in human nature, that must either "rule or ruin." Whether the cost of mining or the reduction of ore will be cheapened, we are not prepared to say. There are many difficulties yet to be overcome; the transportation of ore through four or five miles of tunnel may not lessen the cost, while the old and customary appliances will still be necessary, both for the use of workmen and for hoisting to the level of the tunnel. All things considered, the millions expended must be recovered from the ore, and we fear, though we do not hope, that cheapness will be one of the lost arts on the Comstock. Still, if the tunnel pays for itself, the immense outlay will be justified in the future advantages to accrue in that and other localities, by the solution of so important an engineering problem.

FIRE IN THE MINES.—From Virginia, Nevada, comes news of a fire July 1st, in the old winze of the Imperial mine on the 2100 level. The smoke and gas rushed through the long drift to the Bullion and Exchequer, overwhelming three men, who are still missing. Their names are Donahue, Perry and Cochran. It is not known what fate has befallen them, but probably they have been smothered by the smoke and gas. The drift to the Yellow Jacket new works has been bulkheaded. There were about 75 men in the mines at the time, all but the three above named escaping. The gas was so bad that no man could live in it an instant in the Bullion incline and shaft. As the gas passed toward the Bullion the men were able to bulkhead the drift on the 2000 and on the 2135 levels, south of the burning winze. On the north side the rock is hard, and there are no timbers in the drifts. The fire is therefore confined to the winze, and can do little harm. All was made safe by 9:30 o'clock. Water was sent down into the burning winze by means of an air pipe that runs through it. The fire probably originated from a candle kept near the foot of the old winze, in the drift on the 2135 level.

tion granted by the District Court ordered modified in accordance with above ruling.

A question of subterranean water rights was decided in the case of *Hale vs. McLea*. The defendant had diverted the whole body of a subterranean stream used by plaintiff. The point decided in this case was that the defendant could not exercise any greater rights in respect to the diversion or use of the waters of the subterranean stream flowing across his land to the spring of the plaintiff, than if he had been an upper and the plaintiff a lower riparian owner on a surface stream flowing across their respective lands. The defendant can only claim as much water as he needs for his cattle and for domestic purposes, leaving the surplus to flow to the spring of the plaintiff in its natural channel. But the defendant here had exceeded his rights by diverting the whole body of the water from its natural channel.

AUSTRALIAN EXHIBITIONS.—Dr. J. I. Bleasdale informs us that the commissioners of the Australian International exhibition will keep all of the departments open for the reception of American exhibits until the 1st of March, and at the termination of the Sydney exhibition will be shipped to Melbourne so as to be in time for the exhibition of 1880, at that port. Dr. Bleasdale has made arrangements with the managers of the S. F. Mechanics' fair for the exhibition of all articles intended for Sydney, so that all exhibits may be sent to the forthcoming Mechanics' fair, at the termination of which they will be shipped direct to Sydney. A great many exhibits have been promised, and the public generally are urged to take advantage of the opportunity presented to make a full and valuable exhibit of American industries. California has an interest in this which needs no demonstration. Dr. B. is unsparing in his efforts to make a perfect display of American manufactures. Communications may be sent to Dr. J. I. Bleasdale, care Sec'y Mechanics' Institute, or the New City Hall, or 120 Sutter street.

METEOROLOGICAL SUMMARY FOR JUNE.—The report of the United States Signal Service officer of San Francisco, for the month of June is summarized as follows: The mean height of barometer for the month was 29.913; mean temperature, 59.4; mean humidity, 70.4; prevailing winds, west; highest barometer, 30.103; lowest, 29.766; highest temperature, 85°; lowest 49°; monthly range, 34°; greatest velocity of wind, 30 miles per hour; total number of miles traveled by wind, 8,038; total rainfall, .05 inches. Rainfall in June during former years: 1872, .04 inches; 1873, .02 inches; 1874, .14 inches; 1875, 1.02 inches; 1876, .04 inches; 1877, .01 inches; 1878, .01 inches.

NOTICE TO THE MINING PUBLIC.

MESSRS. RANKIN, BRAYTON & CO., of the Pacific Iron Works, are the only parties authorized to manufacture HOWELL'S IMPROVED WHITE FURNACE under the License of this Company.

THE STETEFELDT FURNACE CO.,

By C. A. STETEFELDT, President.

Referring to the above, the undersigned would call attention to the fact that by a compromise recently effected with the STETEFELDT FURNACE COMPANY, they have secured the use of all the patents of said Company applying to

Revolving Cylinder Furnaces,

And are thus enabled to give purchasers the license of all patent claimants, to-wit:

WHITE, HOWELL, THOMPSON,

— AND THE —

Stetefeldt Furnace Company,

Thereby avoiding all further litigation in reference to these rival claims. The great

SUPERIORITY OF THE FURNACES

Embracing these patents has been satisfactorily demonstrated. There are now some thirty of them in operation in the various mining districts of the coast, operating in all cases with economy and satisfaction, working in many localities

THE BASEST AND MOST REFRACTORY ORES UP TO 90 AND 95 PER CENT.

By an improvement—the patent for which has recently been allowed—this Furnace can be readily adjusted so as to work with equal facility and effectiveness all classes of ores.

The following are some of the Mining Companies who have recently adopted this Furnace, the most of which are now in successful operation, many of them running two and some three and four Furnaces.

NEVADA.—Orand Prize, Star, Martin White, High-bridge, Columbia, Alexander, Paradise Valley, Jefferson, Leopard, Eagle, Endowment, Independence.

ARIZONA.—Tiptop, Tiger, Peck, Hackberry, Corbin, Tombstone, Bradshaw.

OREGON.—Monumental.

MONTANA.—Alice M., Butte City.

MEXICO.—Trinidad, Harniguera, Homoses.

PERU.—Cerro de Pasco.

RANKIN, BRAYTON & CO., Pacific Iron Works.

CAUTION.—All persons are hereby cautioned against buying from other parties Furnaces embracing the improvements covered by the patents above mentioned, as they will be vigorously prosecuted and involved in heavy damages.

WASHING! WASHING!

Prices Reduced! Prices Reduced!

La Grande Laundry,

13th Street, Between Folsom and Howard.

PRINCIPAL OFFICE,

648 Market Street, S. F.

Office open from 7 A. M. to 9 P. M. Saturdays to 11 P. M.

Washing called for and delivered to any part of the city free of charge.

All orders receive prompt attention. For circular and price List apply at the Office,

648 Market St., San Francisco.

PALACE RESTAURANT

218 Sansome St.

(Lunch ready at 10 A. M.) Resident business men and visitors from abroad will be wise in giving this place an early call. Examine of fare and prices.

HERMAN H. HORST, Prop'r.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

RUSSELL'S AMALGAMATOR.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

Pioneer Plating Works.

MANUFACTORY OF

Silver Plated Amalgamating Plates,

For Quartz Mills and Gravel Claims. Are prepared to furnish any size Plate promptly and satisfaction guaranteed. Old Copper Plates purchased, Plated or the Gold Extracted by the most complete process, at small cost, and the copper saved.

JOHN MORRISON, Proprietor.

No. 717 Mission Street, near Third, - - - - - SAN FRANCISCO, CAL.

Barlow J. Smith, M. D.

Consulting Physician,

Professor of Phrenology and Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 638 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervous derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weakness and diseases peculiar to males and females. By the use of hygienic remedies and electro-motopathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-therapeutic, Russian Turkish and Medicinal Baths given daily. Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Phrenology, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the form of the head indicative of the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds. Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' harts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, \$1.50; with charts, from \$2 to \$3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 5 P. M. Sundays from 9 A. M. to 12 M.

PETERSON & OLSSON,

MODEL MAKERS.

INVENTORS

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs), S. F.

Take the Paper that stands by your interests.

J. S. PHILLIPS, M. E.,

Consulting Engineer & Metallurgist,
Examiner of Mines and Assayer,

702 CALIFORNIA STREET,

SAN FRANCISCO.

Author of—
The Explorers', Miners' and Metallurgists' Companion, 672 pages, 83 Illustrations, (2d Edition.) Price.....\$ 10 50

The Greatest Invention of the Age!

MACKINNON PEN.

THE NEW WRITING INSTRUMENT.

24 Gear St., San Francisco.

C. C. Bitner's Apparatus for Obtaining Metallic Copper from its Solutions.

Patented March 11th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides the machinery to run it. For right to use my Precipitator address C. C. BITNER, Spencerville, Nevada County, California.

Continued from page 5.

Gold, 5 ounces; silver, 41 ounces. The Golden King, an extension of the Golden Fleece, produces ore from pay streak 12 inches wide, assaying: Gold, 3 ounces, value, \$82.01; silver, 417 ounces, value, \$492.00; total, \$574.01. At Mineral point the mines are active, with good ore on most of the dumps. In the San Miguel district the Lena, at present working, shows a pay streak of high-grade copper, assaying 800 ounces in silver per ton, with a trace of gold. In the Diamond tunnel the vein is over four feet wide, carrying good ore the entire width. From the Susquehanna 13 tons were sampled and promise a run of at least 250 ounces to the ton. From the Aspen mine, 100 tons of ore have been taken that will average 175 ounces in silver per ton. Rich float has been found in Hensen creek, near the "Burro Cabin," indicating the existence of a valuable silver-bearing vein.

TRIMS.—Denver Tribune, June 25: A new mining camp has been developed about 15 miles from Canon City, at Oak creek, near the fork of the Rosita and Silver Cliff roads. It is called Crystal City. Fifty claims are now being worked; some of them run considerable galena, but many assays as high as 200 ounces per ton. Ship-up and Holt are the principal. From Silver Cliff comes news of a discovery in Wet Mountain valley of a find in Jayhawk tunnel, on Round mountain. Silver nuggets, assaying \$4,337.76 per ton. The Wolf Tonnage is down 36 ft., showing a vein of mineral a foot wide, carrying chlorides—ore assays from 25 to 40 ounces in silver per ton. Rich float is seen 15 feet, entirely in vein matter, without walls. Ore assays 41 ounces silver.

IDAHO.

TRIMS.—Idaho City World, June 24: The Sub Rosa mine has about 200 tons of ore out. The mill was started up yesterday. The mines on the east fork of Salmon are looking well. They are yielding some very high grade ore. A quartz mill is on the road to Challis. There is much snow in the mountains yet, which interferes with prospecting. A rich mine has been discovered near Stanley basin. Several rich mines have been found on the headwaters of Wood and Lost rivers.

TRIMS.—Statesman, June 24: Nine bars of bullion, valued at \$23,530.40, were shipped from Silver City last week. The prospects at Rokey Bar and Atlanta are flattering. A ten-stamp quartz mill is being erected on Shaw's mountain, near Boise City. (News from Bonanza City say that the Silver City mine has at least 2,000 tons of ore in sight, which will average \$200. The Great Mountain mine, at an elevation of 10,000 feet, has a 7-ft vein carrying six ft of ore that will assay \$1,000 per ton. The Chas. Dickens mine is the only mine that has attained any depth. It has a shaft 190 ft deep, with plenty of ore in sight, running from \$200 to \$2,000 per ton. There have been, at the Rising Sun mine, two crushings and cleanups with an astrer, the first showing a residue of nearly \$100 per ton, the second, by the Robertson process, satisfactory, but the result not known. Samples from the tailings of the crushing by the Robertson process submitted to a fire assay and not a trace of gold or silver found in them, showing that by this process every particle of the precious metal is saved. This mine is very rich in sulphurates.

MONTANA.

TRIMS.—Butte Miner, June 24: A discovery of quartz has been made in Spring gulch, a tributary of Alder. Last week, from a few pans of ericite dirt, between \$50 and \$100 in "wire" gold were obtained. The specimens of ore brought to town from the mine, are literally covered with gold. The bullion shipped by express from Butte for the week ending Monday, June 23d, amounted to 2133 pounds, valued at \$34,144.

GOOD ORE.—Northwest, June 20: Several one-horse arastras have been erected for testing the ores at the mouth of Nevada Creek canyon. Yonken & Beesman's 100-stamp-up, which in three days' run is considered a fair average. It is rumored that a rich lead has been discovered at the head of Lincoln gulch, assaying 38 ounces to the ton.

NEW MEXICO.

TRIMS.—Silver City Herald, June 21: Mining in the Minabres is likely to be interfered with by the Apaches. All of the mines are turning out at present very rich ore. Some of the specimens are literally filled with horn silver and other carbonates.

OREGON.

TRIMS.—Jacksonville Sentinel, June 25: Squaw Lake mine is looking well and the depth of the bank of pay gravel is increasing. In the Sugar Pine ledge the supply of gold quartz is abundant. In the Steamboat quartz mine active preparations are being made to find the lost vein. A nugget worth \$140.50 and another worth \$3.25 were picked up near French gulch at the Auburn mines in pipping a claim owned by Mr. R. Roberts. The specimens were fine gold.

Bodie Bullion.

The following is a statement of the total amount of bullion shipped from the Bodie and Standard mines since their discovery, viz:

Standard Bullion.

First bar shipped in April, 1877.			
1877.		June	\$ 83,067.33
May	\$50,034.50	July	104,049.70
June	49,534.43	August	100,510.73
July	55,570.12	September	101,550.19
August	104,704.07	October	70,358.10
September	153,732.77	November	100,507.31
October	123,270.05	December	98,842.75
November	106,239.05	1879.	
December	101,117.11	January	102,167.79
1878.		February	87,700.23
January	80,104.34	March	99,612.39
February	51,040.41	April	102,002.89
March	73,564.29	May	114,851.81
April	73,215.37	June	97,039.30
May	75,540.51		
Total			\$2,366,771.12

Bodie Bullion.

First bar shipped July 30th, 1878.			
1878.		1879.	
August.....	\$601,168.89	Janu'y to M'ch	
September.....	248,530.63	16th.....	\$65,652.94
October.....	85,675.14	June 18th to	
November.....	83,226.74	June 24th....	70,747.13
December.....	87,335.06		

A total for both of \$3,609,483.70. To this amount should be added the bullion shipments of the Bulwer, Noonday, Con, Pacific and one or two other lesser mines, which would increase the total to over \$4,000,000 since Bodie was reopened to the mining world in 1877.

BOSS AMALGAMATOR.—Attention is called to the advertisement in another column of the "Elkins Boss Amalgamator," a machine now being introduced to the mining public and which we illustrated and described in detail in a recent issue. The machines weigh 500 pounds and are useful for amalgamating mill pulp, tailings, sands, etc. They are sold for \$250 each.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CONSTRUCTION FOR WHEELS.—L. B. Lawrence, Monticello, Napa Co. Dated June 10th. This improvement in the construction of wheels consists more especially in a novel construction of the hub of the wheel, and in the employment of a compressed rubber or other elastic holder or socket for the spokes, in combination with a stationary and a movable flange, one being secured to and forming a part of the hub or axle-box, while the other moves upon a screw-thread upon the inner end of said box, and may be set up against the elastic spoke socket disc so that the spokes will be firmly held in place. The invention further consists in the employment of an expanding ring, which is fitted to the exterior of the axle box, so that it may be forced beneath or within the elastic spoke-holder, and when the flanges are screwed up the expander will force the spokes outward, so as to tighten the tire when loose. In wet weather, or when the tire is re-set, the expander can be removed, and the wheel will be prevented from becoming warped by the contraction. Slight impressions in each of the flanges receive the sides of the spoke tenons, which may also be protected by their elastic side washers. The expanding ring may also be steadied by extending it beneath the stationary flange.

BORING IMPLEMENT.—William Heyn, S. F. Dated May 27th. This invention relates to certain improvements in implements for boring; and it consists in a novel construction of a circular cutter, the lower or boring end of which is in shape and form like that of the usual double twisted augers, having a dovetailed or other suitably formed slot, locking or centering device across its diameter, and also two grooves running at right angles from the above-mentioned slot towards a gimlet-pointed screw in the lower or boring end through which the shavings are being discharged towards the operator while boring. In combination with this the inventor employs either a plain and smooth or a partly twisted stem or shank, having a beveled or other suitably formed projection or locking device, which fits those of the circular cutter in such a manner as to unite the two principal and vital parts into one solid whole, thus forming a veritable borer.

DIRECT-ACTING HORSE POWER.—L. Herbert and Wm. V. Henry, Hicksville, Sacramento Co. The improvement consists in mounting on a horizontal bar moving in anti-friction devices between suitable guides, two pulleys which alternately pass in and out of depressions or corrugations formed on the periphery of a horizontal driving wheel, as the wheel is rotated. A rectilinear motion being thus imparted to the driving bar, and power being directly transmitted to a knee lever operating the pitman of a pump or similar device, without the intervention of any gearing.

COUPLING FOR VEHICLES.—John A. Bilz, Pleasanton, Alameda Co. Dated June 17th. This improved coupling for vehicles consists in a novel construction of the circle upon which the forward axis and holster turn to give direction to the vehicle. This circle is cast or formed in one piece, with the extensions which are fastened to the vehicle. It is constructed with a novel king bolt connection which cannot be broken or uncoupled, and it is braced and steadied so that the bolster cannot be tipped over. Elastic cushions relieve wear and prevent rattle and noise. It also consists in certain other details of construction.

CALIFORNIA GOLD MINES.—Hardly one-tenth of the gold quartz ledges of California which are known to exist are worked. Not one-fifth of the gold-bearing gravel deposits of California are worked. Yet the statistics show that many of these deposits which have been worked have yielded more than \$100,000 to the acre. It is a notable fact that very few of the mining interests of California figure on the stock boards. The great mines of Grass Valley are never called. Great mines which have cost millions to develop and the dividends of which are now swelling over a million in the aggregate are not in the stock lists. Once a year something is heard of these mines in the annual reports, and of others nothing is heard because they are not incorporated. It is well to bear these facts in mind. The deposits of precious metals in the somewhat indefinite territory designated as the Pacific coast, have only been here and there explored. The pioneer can no longer take out his ounce in an hour with an old knife and a pan. It requires capital now to open either a gravel or a quartz mine. There are millions of dollars employed in these developments of which we hear nothing, and probably never shall, unless some new quartz district, like the Bodie or Lake, is discovered. Men who are taking gold out of placer mines at the rate of \$100,000 an acre seek no publicity. They pocket the net gains, and at a later day, perhaps, the public find out how A and B are able to put up large blocks of buildings in some of the principal streets of the city.—Bulletin.

"STOCKTON INDUSTRIES."—An article will appear in the next issue of the MINING AND SCIENTIFIC PRESS upon this subject.

The Geological Section.

At the last three meetings of this section of the California Academy of Sciences, the following items of interest were presented by the members:

Mr. F. Gutzkow presented an account of some experiments which he had in hand as to the production of a valuable commercial article of plaster of Paris from the waste sulphate of lime from the chemical works. He exhibited some samples of this improved plaster, and some castings which were made from it. They differ essentially from casts made from the common article, in being translucent, thoroughly crystalline and much harder, so that they cannot be scratched by the finger-nail. They resemble very much in appearance the natural elabaster. Their most valuable quality is, however, that they are impervious to moisture. The plaster seems to be an hydraulic modification of gypsum. Further results are promised when they are obtained.

Mr. Gutzkow also presented the results of some experiments undertaken with a view to the cheap and easy refining of base bullion. The process has for its object the separation of the silver, copper and gold of the alloy. Ferric sulphate is the solvent used. As is well known, this salt has the property of dissolving copper and silver. The ferric sulphate is prepared in the following manner: Copperas, niter and free sulphuric acid in quantities nearly equal to their proper chemical equivalents are heated together in an iron pot, below 100° C. (212° F.) until the red fumes of hyponitric acid are driven off. With the bath thus prepared, the base bullion is digested at a gentle heat, the copper and silver dissolve, while the gold remains as a residue. From the solution of copper and silver sulphates so formed, the silver is thrown down by means of copper. The silver so precipitated is usually contaminated with small amounts of basic salts of iron, but is otherwise pure. The silver from bullion 600 fine came out 930 to 940 fine. Sometimes results as high as 990 were obtained.

Mr. Amos Bowman described the system of mining at present in use at the gold bluffs of the California and Oregon coast. The richest sand is found in a reef of a depth of six to eight feet, which is formed by the surf at some distance from the bluffs, and separated from them by a lagoon of still water. Upon this lagoon lighters are floated which remove the sand from the reef to the depth of six or eight feet by an endless bucket pump. The sand is then run through a system of sluices and amalgamated by means of amalgamated copper plates with the use of sodium amalgam. All the fine gold is said to be saved, and the sand to be worked at an expense of 25 to 50 cents per ton.

Prof. Jos. Le Conte brought up some interesting questions as to the formation of gaylussite (double carbonate of sodium and calcium), in many of our lakes, as Mono lake, in whose waters no lime salts are found. According to Clarence King, this is due to the action of the alkaline carbonates, in which these waters abound, upon the lime salts of the incoming streams, leading to its instantaneous precipitation. Prof. Le Conte desired that anyone who could would send him specimens of the waters and deposits of any of these lakes so that he might investigate this matter. Anything addressed to the "Museum of the University of California, Berkeley," will be sent by Wells, Fargo & Co. free of charge. The water should be sent in clean bottles carefully sealed.

An interesting discussion upon the origin of gold quartz veins, and upon the cause of the variable fineness of placer gold then followed, in which all participated. Prof. Price presenting the results of years of observation and careful assays upon the latter question, and Mr. S. B. Christy presenting the results of some experiments bearing upon the former question. Further investigations were promised by both these gentlemen.

Messrs. C. A. Stetefeldt and Ross E. Browne were elected to membership.

ODD FELLOWS' LIBRARY ASSOCIATION.—We are pleased to note the increase of the above library. It appears from the 24th annual report for 1878-9 that 1,665 volumes have been purchased during the past year, and 90 volumes donated. The reading room is well supplied not only with Pacific coast journals, but with all the leading American, English and German newspapers and periodicals. The total number of volumes in the library is 33,500. The circulation for the year was 107,512 volumes, an excess of last year by 3,502 volumes. From the statistics it appears that 86,427 novels were drawn out to 355 theological and 2,814 scientific works, a result which appears in the published statistics of every library. The cabinet connected with the library contains many valuable and interesting articles. George A. Carnes is the librarian, and to him we are indebted for a copy of the neat report.

REMOVING SCALE FROM BOILERS.—If the boiler is not a very small one, add once a week, about one pound of soda (sodium carbonate) for every 50 gallons of the boiler's contents, taking care to blow out (through the bottom blow-out tap) this charge with the accumulated sludge before adding more, and meanwhile do not let the water run low in the boiler.

News in Brief.

NIHILISM in Russia is nothing. ANARCHY prevails in southern Epirus. FROSTS are doing damage in Lassen county. WATERMELONS are now a staple in San Diego. MOLLIE McCARTY won the 2½-mile race at Chicago in 4:02.

THE Prince Imperial was deserted by English troops in Zululand.

ANTI-LANDLORD agitation in the west of Ireland is becoming serious.

THE Khedive of Egypt no longer reigns. He has abdicated—gone to Naples.

IN Dakota and northwestern Iowa, the grass-boppers are again ravaging.

IN the Bank of France the past week specie increased 19,270,000 francs.

THE potato blight is troubling the river bottoms of Washington Territory.

REDEMPTING subsidiary silver coin with standard dollars does not work well.

THE northern Indians, having been whipped, are now willing to go upon their reservations.

SAN BUENAVENTURA has now two oil refineries in operation, and another one building.

A BAD harvest is expected in England. Prices are increasing and American wheat in demand.

AN Eastern paper writes an editorial begging the President not to veto the adjournment of Congress.

AT Liverpool, 30th ult., wheat was quoted at 8s 4d@9s 2d for average California white, and 9s 1d@9s 5d for club.

BISMARCK has been openly snubbed by the Empress of Prussia for declining to recognize the divine right of kings.

CONGRESS has adjourned without making any provision for United States Marshals. How does Congress expect them to live?

NITRO-GLYCERINE works at North Adams, Mass., exploded recently—distributing two men and the adjacent buildings.

THE Mayor of San Francisco refuses to sign the new tax levy because it is 17 cents more than he thinks it ought to be.

THE receipts of the Sunday School picnic last Thursday, amounted to \$374.65. Net proceeds \$321.85 distributed among Relief Societies.

THE time for receiving applications for space at the International exhibition at Melbourne has been extended to October 31st, 1879.

THE French journals claim that the Darien canal will be absolutely neutral territory. Absolutism does not accord with American ideas.

IN San Francisco half dollars are quoted at 99 buying, 99½ selling; trade dollars, 98 buying, 98 selling; Mexican dollars, 93 buying, 93 selling.

IT is said that since the prevalence of cyclones in Missouri, and their regular appearance, the farmers are driving posts into the ground to hang to when they come.

THE corporations of San Francisco during the month of June last, disbursed in dividends the sum of \$955,666, a falling off over the same month in 1878 of \$1,245,042.

ABOUT 2,000 people attended the meetings of the Monterey Sunday School Convention June 29th. Every portion of the State except southern California is well represented.

AT Oakland last Saturday, the quiet but forcibly expressed indignation of citizens, procured the withdrawal of 300 Chinamen from works on Long wharf. There was no open demonstration.

THE Suto tunnel is now an accomplished fact. Pumping commenced June 30th, and in eight hours the water in the drowned out mines was lowered 100 feet. The temperature of the water at the mouth of the tunnel was 118°.

THE Catholic Church has 64 cardinals—32 Italians, 10 Frenchmen, 4 Spaniards, 4 Austrians, 3 Hungarians, 3 Englishmen, 2 Portuguese, 1 American, 1 Belgian, 1 Pole, 1 Bavarian, 1 Corsican and 1 German.

CREMATION having been pronounced a measure of "salutary progress" by the committee of the Paris Municipal Council appointed to consider the question, is about to be introduced into Pere La Chaise Cemetery. It has been decided to set up an apparatus on Siemens' principle, and a Columbarium.

A GIRL 17 years of age, at Boudon, Ontario, is said to be a perfect electric battery. Very few can shake hands with her. By joining hands she can send a sharp shock through 15 or 20 people. Her magnetic attraction is so great that she cannot let go of any article of steel she has picked up. A paper of needles will hang suspended from her finger.

THE Congregational Association, which has been in session at Seattle for a week, adjourned Saturday evening, to hold the next annual session at Fidalgo. The Association endorsed the Massachusetts Civil Damage law, and will seek like legislation in this Territory. The ministers in the Association were requested to preach at least one sermon in the year on the observance of the Sabbath.

BERKELEY PROPERTY.—Many people find Berkeley property desirable for residence, both for the inherent beauty of the location, its nearness and accessibility to the city and its educational advantages. Many move to Berkeley that their sons and daughters may live at home while pursuing their courses at the State University, and some have secured lots and built cottages in which the young people keep house for themselves. Those who may think of Berkeley for a home or for investment will be interested in the advertisement of Mr. Penwell in another column.

Butts' Fruit, Vegetable and Hop Drier.

The enormous and continually increasing demand for canned and dried California fruits, and the production of available quantities, has aroused the inventive faculties in the direction of economical and perfect processes for supplying the market. Mr. Wm. Butts, southeast corner Spear and Mission streets, S. F., is the patentee of a fruit, vegetable and hop drier, which seems worthy the attention of manufacturers and farmers. The Butts drier is built in sections, each of which is complete in itself and of a capacity of 1,500 to 2,000 pounds per day, all the sections are precisely the same cut of lumber, and to any person desiring a large drier, several sections are placed together. Put together with screws, the apparatus is so arranged as to be easily taken apart and transported to any distance in a portable shape.

The fruit is placed in the drier upon a series of trays, and the drying heat conveyed to the whole interior or to any particular tray by simple valves or dampers regulated at pleasure from the outside by means of a uniform key. By means of these valves, easily regulated, the fruit, when ready for packing, need not be removed from the drier, but may remain for any length of time, without deterioration, until necessary to be removed to give room for a fresh supply, the drying heat being shut off. This feature, it is claimed, is different from other driers, and the inconveniences of over-drying, etc., entirely avoided; saving the labor of handling movable trays and economy in the fruit by securing uniformity of appearance and quality. The fruit does not require any manipulation by acids, etc., before, or any sorting after drying, it is put into the drier in its natural state, preserves its color without oxidation, and comes from the drier speedily, ready for immediate packing, shipment or storage. The apparatus is self-ventilating, and all the moist air arising from the fruit is carried off immediately and perfectly. It is also claimed that 160° of heat in this process will accomplish the same results as 300° in others, and with better results, brought about by a peculiar arrangement of side drafts all under control from the outside.

In the drying of hops this process is peculiarly valuable, as it has practically succeeded in the difficult task of drying hops without destroying their qualities by over-drying or inducing incipient fermentation by imperfect drying. The hop drier now being successfully used by Orrin Howell at Hopland, Mendocino county, is said to be a visible proof of the claims of the inventor.

Another feature of Mr. Butts' apparatus is a fruit "canner." In the canner, the fruit is put into the cans raw and sealed, then placed in trays, carrying say 150 pounds each, easily handled, and cooked. It would seem practicable for all of our fruit raisers to utilize their surplus fruits either by drying or canning, thus making them more marketable and command a better price than in a crude state. Several farmers could combine in the matter, and as fruit drying and canning is no longer an experiment hut, when wisely managed, an actual profitable investment, there could not be any danger of failure to realize pecuniary benefits. Specimens of fruits, vegetables, meats, fish, etc., dried by this process can be seen by calling upon Mr. Butts, and their appearance and quality would seem to justify his claims.

EVERY new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

PRINTER'S PROOF PRESS, complete and in good working order, for sale at this office, at the low price of \$30. Call and see it.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

DEWEY & CO'S

SCIENTIFIC PRESS

Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address.

DEWEY & CO.,

292 Sansome St., N. E. Cor. Pine, San Francisco.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia, and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

FRASER & CHALMERS
 STEAM ENGINES, BOILERS, STAMP MILLS, FRUEVANNERS
 (and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores
 No 145 Fulton St. CHICAGO, ILL.

Dunham, Carrigan & Co.,

Nos. 107, 109 & 111 Front Street, S. F.

Lathe Without Saw Attachments.

This lathe has been made especially to meet a want felt by many for a really good and substantially improved lathe at a reasonable price, and we think that it is by far the best lathe ever placed on the market at the price asked. The bed, head, and tail stocks are of iron; the spindles of steel. The bearing of the head stock is conical, so that the wear can be easily taken up.

Material eighteen inches long and eight inches in diameter can be turned upon it. The pieces thus accompanying this lathe without extra charge are two T rests, two plain centers, one spur center for wood turning, and one face plate.

Price of Lathe without Saw Attachments.....\$45. Price of Lathe with Scroll Saw Attachment.....\$55.
 Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills $\frac{1}{4}$ and under, Price.....\$1.50
 Chuck for drills $\frac{1}{2}$ and under, Price.....\$2.25
 They are made on solid steel plug, centered and readily fitted to Lathe or Drill Press.
 SEND FOR CIRCULAR.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

STEEL CASTINGS.

From 1-4 to 10,000 lbs. Weight.
 True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties.
 Circulars and Price Lists free. Address

Chester Steel Castings Co.

Works, Chester, Pennsylvania. 407 Library St., Philadelphia

Union Brass Foundry and Mechanical Work Shop.

GIOVANNINI & CO.,

417 and 419 Mission Street, - - SAN FRANCISCO.

The attention of our customers and especially of those interested in Water Works, Gas Works or Mines is respectfully called to our very important improvement in the construction of Stop Valves (or Gates). They differ from all others in that the inner faces are perfectly parallel, therefore when the Gate or Valve is to be opened, at the first movement of the screw the center block (see cut) releases the disks from their bearings, so that they will move easily and prevent the wearing of the inner faces.

This Gate has proved very efficient in Pipes of all sizes, and under any pressure and from its double form and perfect joint formation is especially valuable for use in large Pipes for water, steam and gas, and from its avoidance of any wedge shape cannot jam at any point (see cut).

The G. & B. Valves (or Gates) have no equal in simplicity of construction of all working parts, ease of access for repairs, and durability. We have recently enlarged and fitted up our Brass Foundry and Shop with all the latest improved Tools and Machinery, thus greatly increasing our facilities for rapidly executing orders for all sizes of Stop Valves (or Gates) from three-inch to four feet in diameter, or any size, to order. We guarantee them to give better satisfaction, cost less money, and last longer than any other Valve in use.

We are also prepared to execute all orders in Brass Work for Drowlers, Distilleries, Plumbers, Gas and Mining Apparatus, Ship Work, Soda Apparatus, Steam Fittings, Meters, Gauges and Indicators. Also in Machine Pattern and Model Making, and Clock Work. Gear cut to order. Brass Castings of all kinds. We are confident of our ability, and all orders entrusted to us will be executed with promptness and dispatch.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

SHEET IRON PIPE.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS
Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive.

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ^{1/2} Triple Force Caps and all Grades of Fuse.

PAUL'S AMERICANIZED ARASTRA.
"Is working splendidly and giving complete satisfaction." So say those who are using it. This is a perfect Amalgamator and Pulverizer. It combines all the virtues of the Mexican Arastra, with every modern device to make it thoroughly efficient, expeditious and practical. It will do more work and do it better than any mining machinery for double the cost. Call and see it, or send for circulars to **ALMARIN B. PAUL,** room 20, Safe Deposit Building, San Francisco.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Publishers.

SAN FRANCISCO, SATURDAY, JULY 12, 1879.

VOLUME XXXIX
Number 2.

Tucson, Arizona.

We learn from "Hiuton's Handbook to Arizona" and other sources, that the early origin of Tucson is obscure. It is claimed that the valley was settled about the year 1560, which would make it the oldest city in the United States except Santa Fe, which was settled in 1555. Three miles below Tucson, and one mile east of the mission of San Augustin are the ruins of an old town, but no clue can be obtained as to its origin, history, or the date and circumstances of its destruction.

The lands near Tucson are very rich and were once extensively cultivated, but the Apaches compelled the people to abandon their ranches and seek safety within the town.

The climate is one of considerable range; frequent frosts at night in winter, succeeded by weather comfortably warm during the day. The summers are quite hot, with a sufficient fall of temperature at night to make comfortable sleeping. The spring and fall are quite variable. A little stream flows past the town, the water from which keeps the valley perennially green.

How like a *fata morgana* it looks when you first see it in this enchanted atmosphere: the intensely blue sky overhead, the plain above it covered with sparse grass and fantastic cactus, that hide the sand and make the earth look verdant; the low, white dome and the picturesque buildings clustering about it; the adobe garden walls, with arched gateways, sometimes whitened, sometimes left in their native mud color, toned down by age and the glare of the sun; a tall mesquite tree, or a group of cottonwoods striving heavenward from among the adobe houses; Saddle mountain, with its ever changing tints and its strong lights and shades in the far distance, and Sugar-loaf or Sentinel hill to the immediate left. On the plain between town and the Sugar-loaf, the ruins of what in any other country I should pronounce to have been a monastery, lift themselves from the fresh dewy green—venerable, gray and stately—some wild vine creeping stealthily in at the frameless window, and out again at the roofless top.

Tucson is seen to be located about two-thirds of the way southeast, on a huge plain or plateau, which presents many very striking features. The wonderful effects of the clear and rarified atmosphere are seen here at their best. The great plain or plateau in which just above this place the Santa Cruz sinks for many miles, to enter by a subterranean channel the Gila river, near Maricopa Wells, is certainly over 100 miles in its greatest length and not less than 50 at its widest, which, from the trend of the encircling mountain ranges, is in this vicinity. Looking north and west the eye rests upon the deep blue faint outlines of ranges at a distance of at least 75 miles. Nearer and in the wonderful foreground, which is one of the most charming effects seen here, to the east and west may be seen the bold cones of the Picacho and Desert peaks. They stand out in the translucent sky and the luminous sunrise or sunset, with their wonderful combination of colors, so vivid and startling as to defy even the brush of Turner himself, as if one might walk over to them between breakfast and the gray glooming which indicates that the night has passed. Nearer and closer, until their serrated summits seem about to bow down to us, on the east, trending from the northwest to the southeast, is a bold and remarkably well-defined mountain range known as the Santa Catalina, which sweeps in a bold semi-circle, framing the Santa Cruz valley in a massive way. The range lowers and a pass opens just to the east of Tucson. The continuing portion of the range is sometimes called the Rincon mountains. It looks wonderfully and fascinatingly beautiful—the deep shadows and purple tones in which the sunset clothed its sides, while the mirage, which accompanies sunrise and sunset in this latitude, and plays such

"fantastic tricks" to startle our vision with, gave to the summit lines and peak tops new and shifting images and forms. It is difficult to realize as one looks at the landscape here, that some of the green fields in which Tucson is set like a dark pebble in an emerald border have been under continuous cultivation for over 150 years. Contemporaneously the Pilgrims landed at Plymouth Rock, and that other fateful cargo had been placed on the banks of the James river, in Virginia; the Spanish conquerors of Mexico had established a presidio at this point, and the Jesuit Fathers had raised the symbol of Christianity, and erected houses of worship amid savage tribes and in the very heart of a wilderness. The town of Tucson then became the presidio of Tucson. North of this point there was no settlement or mission, nor west of it either, the Puerta de San Diego being the nearest in that direction. Tucson was then, as now, the principal place in the Territory. It still stands as the representative of the old semi-Spanish-Indian civilization; for the Mexicans comprise two-thirds of the resident population, and "the Church" occupies, with its offices, the place of honor customarily assigned to it in the laying out of a Spanish-American town—the principal portion of the chief plaza or grand

of the Apache nation in Arizona was subjugated. Many reguades, however, continued to infest the rich mineral districts of this country until 1877, when they were finally killed or driven out by the hardy pioneer and prospector with rifle in one hand and pick in the other, with his canteen with water and beans on his back he faced the treacherous red devils, until the reguade Apaches is heard of no more. In Arizona as in California, the peace, the prosperity, which now dawns upon them is largely due to the indefatigable, the brave and stout-hearted miner, prospector and farming pioneers.

The richness of the mines is now an accomplished fact, and improved appliances rapidly bringing to light this wealth so eagerly sought in times gone by at the risk of the miner's life. And the Tombstone, as early as 1860, declared by its discoverer, Bronkow, to be the richest mineral district in this territory, has, by late developments, placed him upon record as a true prophet, finding his babulism for prophecy, bowsver, in known facts.

Railroad communication, so soon to bring Tucson within reach of a market and to bring her within the pale of mechanical civilization, will remove any doubts about her future that

Intersecting Cable Wires.

We have been shown this model of an invention for wire cable grips, whereby a crossing can be effected at intersections. The inventor is Vitruvius Frazes, architect, 137 Montgomery street, S. F., and his invention solves a multitude of problems connected with traffic over cable roads. The object of this invention is to furnish a means by which cars propelled by a cable running beneath other cables may cross such cables without any appreciable interruption, and without any special care on the part of the engineer. The cars to which it is attached may be stopped and started at any point on a crossing. The cable is always within the dies when crossing another cable, and the dies may be tightened or loosened at any point. No interchange of signals between cars of intersecting lines is necessary, because they may pass immediately in advance or in the rear of each other without any interference of their cables. The device has also another advantage in that it may be constructed to carry the cable to which it attaches anywhere from 9 to 16 inches below the surface, and however it may carry a cable it can cross any number of cables lying at various depths below the surface without touching any of them. Three notched-wheels revolving in a nearly continuous flange, each wheel having three semi-circular notches or openings somewhat larger than the cable to be passed, are attached to this lower gear or grip of the car. The flange is broken only to admit the intersecting cable passing through at right angles, the passing cables turning the notched wheel and directing the cable into the next wheel and so on until passed.

The lower gear of this grip—that part below the notched wheels—is provided with an inclined plane projecting out in front of it, which forces the cross cables upon a pulley attached to a stationary cable lifter, and thence on and in between the notched wheels. The cable runs through between the grip and sliding bar into the wheels as perfectly as if an open unencumbered lot or passage existed, and the grip upon the drawing cable being maintained without any exertion. The whole contrivance works automatically, and what would seem to be difficult to overcome is overcome in a simple manner.

The grip itself is composed of a number of small pieces resting upon a rubber base or foundation so as to distribute the force or strain over many parts, instead of one, thus saving the wire. This latter is a device unconnected with the crossing contrivance. We shall have occasion in a future number to illustrate this invention more perfectly than can be done in a written description.

REDUCING THE ESTIMATES.—It is not long since the Colorado press was computing the billion product of Leadville for the current year at something like \$100,000,000. Their present figure is \$11,000,000, about the annual yield of Eureka, Nevada, a camp concerning which little is heard compared with the much said about Leadville. We hope there will be no cause for further reducing the billion output of Leadville, the monetary world having adjusted itself for a large influx of silver from that source.

JUSTICE IN ENGLISH COURTS.—The English bondholders of the ill-famed Emma mine of Utah, brought suit against Lewis & Son, metal brokers in Liverpool, to recover damages on the ground that they had conspired with Treanor W. Park and others, to cheat the plaintiffs. The jury found for the bondholders, to whom they awarded \$40,000 damages, value of the stock assigned defendants by their coadjutors.

WASHINGTON TERRITORY last year exported 160,000 tons of coal and 21,000,000 feet of lumber. Over 600 ocean vessels arrived and departed in the same time.

CITY OF TUCSON, ARIZONA.

square thereof. A map of Arizona will show the value of this point as a trading post, and will indicate also its future importance, provided always the railroads going east and south shall pass through it. Tucson is now the central point on the overland route, and for communication with Sonora. It is the seat of the nearest United States Custom House thereto.

The engraving on this page, taken from "Picturesque Arizona," published by the Continent Stereoscopic Co., of New York, represents Tucson as it appeared in 1877.

Of late the mining industry of Pima county has been rapidly developed, particularly by the rich strikes made in the Tombstone district and other localities.

The blood-thirsty Apaches murdered the early miners and destroyed the mining appliances, and what the Indians left intact the Mexicans destroyed, and it was not until the Camp Grant massacre of the spring of 1871 that the long outraged people of Pima county took the settlement of the Indian question into their own hands, and, trailing the thieving, murdering, blood-thirsty Apaches, with the plunder they had stolen, into Camp Grant Indian reservation—their city of refuge—then and there our people made them atone for the hundreds of innocent lives they had treacherously and barbarously taken.

This good piece of work was the means of the government sending General Crook to take command of this department, whose Indian policy brought the Indian question to a successful issue, and at the close of 1874 the great body

her timid citizens may possess engendered by reading old archives.

PUBLIC STEAM HEATING.—A project to introduce public steam heating in New York has been sanctioned by the Commissioners of the Sinking Fund. The system is known as "Holly's steam combination system" for heating, cooking, and other purposes. It is claimed that by it there will be a saving of \$150,000 a year in the heating of the public buildings. It will also save the city from \$300,000 to \$500,000 per annum in the removal of ashes from the dwellings and snow and ice from the principal streets and avenues. The steam will be conveyed through pipes laid in the street, and supplied for any purpose. Its cleanliness and many advantages to the housekeeper cannot be estimated too highly. The city is to receive \$150,000 from the company for permission to lay the pipes, and a further compensation of 3% of the earnings of the company. That section of the city south of Canal street is set apart for the purpose.

The shrinkage of values does not seem to have affected the price of seats in the New York Stock Exchange. A gentleman, anxious for the right to buy and sell in the charmed enclosure, bid \$11,500 for a seat, at auction last month—the highest price ever paid.

TWO HUNDRED AND FIFTY emigrants from Iceland are en route to Minnesota.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS

Carson and Vicinity.

EDITORS PRESS:—The progress of Carson, the silver capital, in conconnection with the general progress of the great mineral State, is one very clearly marked from year to year, though not with entire uniformity. The lands in the vicinity, reclaimed by irrigation from the dry, sage brush plain, are more extended. The fields and gardens are better cultivated. Lives of trees, groves, orchards, and ornamental shade trees are increasing in size and beauty. Family residences and permanent buildings are gathering all lovely attractions around them, while within the neatness and adornments and luxuries of life, are greatly increasing. The stores, shops, manufactories, hotels, and business houses are larger, better supplied and finer in interior and external appearance; the streets are in good order, level, graded by nature, and free from mud. The two public school buildings, the three churches, the State capitol, and United States Mint, are of their kind fine structures, each in character with its design. The streets and houses are lighted by gas, and the whole city, in all parts, is well supplied with abundance of the best of water.

The scenery around is romantic, rugged and grand. A little to the west, perhaps a mile and a half, the great, varied Sierran range rises abruptly near four thousand feet into the heavens, with summits rarely if ever entirely free from snow, with sides once wooded nearly to the tops now mostly cut away for lumber and firewood in the mines. To the north and south barren spurs from the Sierras, broken and irregular, extend across to the east to connect with higher ranges, running north and south, shutting in the regions of the city as one enclosed, even, pleasant valley; one which might be made to flourish as a garden in beauty, if a large irrigating ditch could be dug for the watering of the whole. This can be done, and will be ultimately, when needed by the immense population which must dwell in America a hundred and twenty years from now. This, at the rate we have increased the last hundred years, will be over 1,600,000,000 of people. We shall soon need all the land possibly available for cultivation for our own population, without any from Asia.

Though this valley appears shut in, yet the Carson river, coming down from the south, passes along the eastern edge and cuts its zig-zag deep canyon way through the eastern ranges on to its lake of evaporation, sixty miles to the northeast. Down this river, from forests in the mountains at its head, are floated some 60,000 cords of wood yearly for use in the mines and mining towns. Yet this is not probably over one-fourth of the amount of wood and timber used in connection with all the mining in the region. The larger supply comes by the railroad, some even from California, but much of it reaching the road by long water V-flumes or chutes, bringing down the wood from the region of forests seven, or even twenty, miles away in the mountains. By this process thousands of acres of timbered lands on the eastern steep slope of the Sierras, are being yearly swept clean of all trees, left, in appearance, as barren as if they never had any growth of trees upon them. Some scientists say this will cause these slopes to be forever barren, and diminish the already very slight fall of rain through the whole country. We very much doubt this, for if so then the denuding of more than one-half the vast region of continuous forests east of the lower Mississippi, Ohio and Missouri rivers to the Atlantic ocean, and the covering of the immense prairies of Illinois, Missouri, Iowa and Wisconsin with cultivated groves of trees ought to have produced decided changes in the rainfall, proved so by reliable statistics. Certainly such denudation does affect the springs and the moisture in the soil, and also the uniform flow of the streams and rivers; yet we doubt its very sensible effect upon the average fall of rain.

Chicken Soup Spring.

There is, a mile and a quarter north of Carson in the open plains, a large hot flowing spring. Its perfect analysis has not been made, but there is a little sulphur with iron, manganese, etc., in such very moderate quantities that the fountain appears to differ but little from that of common hot water. But by merely stirring into a bowl or glass of it some common salt and pepper the color changes to accord with the taste, which is so like good palatable chicken soup, a stranger would not detect the difference. Certainly, to us, the resemblance was perfect, as we drank it, and we believe that had it been given us in the city at a restaurant for chicken soup, we should not have detected the imposition. The water is also said to be excellent for all rheumatic and kindred disorders, and is remarkably excellent for bathing, producing no lassitude like other hot springs by one remaining in it a length of time.

In the hills surrounding Carson and its beautiful valley quite a number of mining claims have been laid and partially opened, some with really encouraging prospects. Still, as yet, none of them have been made to pay the expenses of working. Copper, lead, antimony, silver, gold, iron and even coal have been found, and in time these may be worked to advantage, though not at present.

S. V. B.

Mono County Mining Interests.—No. 1.

EDITORS PRESS:—The people of Bodie are as much excited over its own prospects as are the stock dealers of San Francisco; and this seems like a strong statement. Hundreds of mines are everyday expecting and likely to encounter rich ore, though most of them are running prospecting shafts only. There are quartz ledges varying from one inch to 13 feet in thickness. The Bodie mine is producing the richest ore, and the ledges are now found dipping to the east. As worked heretofore the mineral ledge had a dip to the west; recently, however, they became vertical and appeared to be pinching out; now they find them dipping to the east and increasing in value and width. Another notable fact is, that the amount of silver in the alloy is fast increasing, which, according to precedent, would indicate a permanence in the production, and eventually, the encountering of silver as the predominating metal, as has been found to be the case in Nevada. Furthermore, from this we may conclude that Bodie camp is not one of the wildcat kind, but one which is to produce largely as deep down as it becomes practicable for machinery to work.

The 206 level of the Bodie mine is producing from a ledge two feet wide a mineral which is fairly spangled with gold. The gangue is a crystalline quartz of a gravelly consistency, occasionally holding crystals well developed, and the whole is of such a nature that a blow with a pick or hammer breaks it into small pieces. The veins seem richest at the point of contact with the wall, and here is found a fine red clay; it seems to have penetrated the vein matter in mechanical solution and remains a plastic mass, which has to be dried before milling. On the 430 level is found a vein whose gangue is of harder and purer quartz, containing the same clay and whose richness shows a higher figure than anything of the kind ever met. As some have remarked: "It hardly decreases in volume when washed." In many instances the precious metal holds the quartz together as the cementing material of an ordinary conglomerate. No water troubles the Bodie mine on either level, but the ventilation is not as good as it should be. There is a dependency on the atmosphere, which in this district, 9,000 feet above the level of the sea, is rendered unreliable on account of its extreme lightness at times. Attention to the matter would insure better labor and more of it from those employed underground. We are assured that on the day of our visit it was unusually bad.

The Standard company produces more ore than any of the others; ore of a quality not as valuable as that from the Bodie, but rich enough to pay a very large profit on milling. The Standard company now has three shafts running constantly: The Standard proper, the new Standard and the double Standard. The first is producing most of the ore crushed at the Standard mill; the second, the new Standard, is so flooded with water as to be unable to produce much ore at present, the heavy pumping machinery being erected will soon put them in condition for hoisting out ore with facility; the third or double Standard has not as yet found any paying ore, but has just begun the erection of extensive hoisting works to supplant the horse power heretofore employed. The Syndicate mill is running on ore from the New Standard mine.

The Summit is getting out ore now, but crushing none at present. The one custom mill, the Miners' mill, is crushing for the Noonday mine, which has considerable ore on hand.

J. H. W.

Bodie, June 30th, 1879.

Breaking up Slag with Rock Salt.

EDITORS PRESS:—An item gathered in Carson we judge worthy of especial note for the benefit of all, gas makers in particular. In the furnaces of gas works there always gathers a very hard, solid slag; very difficult to remove even with iron bars. The attendant in the works at Carson told us, that, by accident, he found that throwing in onto this hot slag, after the coke was drawn out, a handful or so of common rock salt rendered this slag, in a few minutes, easily drawn out like coarse, pebbly sand. If one handful should not loosen up the whole mass, another handful could be also thrown in, and the result was certain; the slag could all be drawn forward the same as ashes. This fact must be of thousands of dollars value to the many gas manufacturers in the land, and it is free for their use. Experimenting will make evident the best manner of using the salt for the purpose.

Carson, Nev.

MAGNETIZATION OF NICKEL.—According to M. Henri Becquerel, in the *Comptes Rendus*, bars of nickel become saturated with magnetism much more promptly than iron bars, and hence are better suited for temporary magnetization—a fact which might be useful in telegraphy. Cobalt gives results similar to nickel.

THE HOLLY SYSTEM of heating by steam is about to be tested in the city of New York on the lower end of Canal street. Pipes are to be laid in the street and steam supplied for all household and mechanical purposes.

Brains.

Brains, though rare, are not distributed by any known rule among a particular class of people. A Stephenson may be born in the cottage of a common miner, and rise to teach the world the science of engineering. A Franklin may force his way from a printer's case to the position of a great statesman and a great physicist. Opportunities are what are required, and lacking the opportunity there would not have been any Stephenson nor any Franklin. Comparatively few men of ability are born every year, but they are as likely, perhaps more likely, to be found in the humble dwelling as in the palace. The important problem for any country is, how to utilize its most valuable raw material so as to get the greatest possible effect from it. In the case of brains the answer is simple: give their owners an opportunity to get an education by which their mental faculties can be afforded an opportunity of being used to advantage. Bring out their natural abilities. If the boys about a mine or in industrial communities, instead of spending their leisure hours in taverns or even worse places of resort, listening to the harangues of demagogues upon the wrongs of the workmen, should utilize them in a school where a technical education could be imparted, they would with an increase of knowledge take more interest in the prosperity of the country, and have more confidence in the stability of government, and believe that there is a future open to them worth working for. When witnessing the utter demoralization of many of our youth, who does not recall the words of Dikeus, "There is not one of these poor creatures but sows a harvest that mankind must reap." The poor working classes have their wrongs, but in a great measure they are brought about by the sudden elevation of some of their own number using oppression, through deficient education, or by their own excesses or indolence.

Between practical foremen and educated engineers there exists a jealousy which must be wiped out by the inculcation of a higher education and opportunities to develop. The resources of the locality where is the domicile, the home, must govern the educational course—mines in a mining region—agriculture in a farming region—and cosmopolitan studies in the cities—otherwise the mind finds its surroundings uncongenial and is dwarfed. Like a tree transplanted to an unaccustomed soil and climate it withers and dies, or lingers through a sickly existence. Preaching about the evils that beset communities will do no good. Practical common sense must apply a remedy.

On the Metallurgy of Platinum and Iridium.

Contributions to the metallurgy of the metals of the platinum group are so rare, and the information given in text books so meager, unsatisfactory and superannuated, that a brief description of present practice will be welcome. This has been furnished recently by Mr. George Matthey, of the famous platinum smelting and manufacturing firm of Johnson, Matthey & Co., of London, in a paper read before the Royal Society. According to this—probably the best authority living—the commercial platinum is melted with six times its own weight of pure lead, the alloy granulated and treated in dilute nitric acid until fresh acid fails to act. This dissolves out the greater part of the lead, and the copper, iron, palladium or rhodium which may be present. The residue, a black powder, is dissolved with weak *aqua regia*, which leaves behind a residue consisting of all of the iridium and a portion of the platinum contained in the black powder. After evaporation of the solution of the chlorides of lead and platinum a sufficient amount of sulphuric acid is added to effect the precipitation of the lead as sulphate. The chloride of platinum is dissolved out with distilled water, and precipitated with an excess of chloride of ammonium and sodium. The whole is then heated and allowed to stand for some days, the ammonio-chloride of platinum settling down as a fine deposit, while any sodium, if present, will remain in solution, which has a rose tinge therefrom. In order to effect a purification of the platinum precipitate, it is dried, and after adding bisulphate of potash, with a small proportion of bisulphate of ammonia, it is subjected slowly to a dull red heat. The platinum is reduced to a black, spongy, porous mass, while the rhodium is obtained in the shape of a bisulphate of rhodium and potash, soluble by digesting with boiling distilled water. A small quantity, it is true, is dissolved as a sulphate together with the rhodium salt, but it is regained by heating the residue after evaporation to redness, at which heat the platinum salt is reduced to a metallic condition, while the sodium salts remain undecomposed. The platinum obtained as a spongy mass from the heating of the chlorides is melted, and yields a pure metal, having a specific gravity of 21.46, the highest attainable. The iridium obtainable from its ordinary solution is quite impure. Mr. Matthey fuses it with lead, dissolves out the lead with nitric acid, and fuses the residue with bisulphate of potash, by which the rhodium is removed. Then it is melted with 10 parts of caustic potash and three parts of nitric for a

long time, and the cold product is lixiviated with water, which dissolves out the ruthenate of potash, while the corresponding iridium salt remains behind as a blue powder which, after being washed with hypochlorite of soda, is mixed with a strong solution of that reagent and slowly heated to the boiling point in a distilling vessel, thus removing the ruthenium. The blue powder is then dissolved again in *aqua regia*, evaporated to dryness, redissolved in water, filtered, and the dark colored solution thus obtained poured into a concentrated solution of soda and hypochlorite of soda. Iridium is then precipitated as an oxide by passing chlorine through the solution, and the precipitate so obtained is reduced by the combined action of carbon and carbonic oxide, generated by heating gently a mixture of oxalic and sulphuric acid. The metal so prepared is purified by subjecting it to the action of chloric water and hydrochloric acid, and is then cast into ingots, having a maximum specific gravity of 22.33. Mr. Matthey uses the metal in the preparation of malleable and ductile alloys of platinum and iridium, holding 10% to 20% of the latter. These are claimed to combine the more valuable physical properties of both the metals in an exceptional manner. It has much of the malleability of platinum and the hardness of pure iridium.

Hypnotism and Science.

Mankind, in hot pursuit of pleasures and the wherewith to procure them, are hardly aware of the silent labor bestowed upon their amelioration by those engaged in scientific investigation. Periodically an astonishing discovery is made, some hidden force of nature is utilized, and the world amazed stops, adopts the convenient discovery, and then, condemning it by reason of that familiarity which breeds contempt, rushes on again in its mad whirl of physical excitement. Too much devotion to the purely physical development has always, and perhaps will always, prevail. The pure, theoretical pleasures of the mind are to a great extent wholly disregarded. Perhaps science is not altogether blameless for this condition of things. Monotony of any description cloy the reasoning faculties, and excites finally distaste and abandonment. From the purely speculative philosophy of the ancients, we have as a matter of course fallen into the opposite extreme, obeying, humanly speaking, that law of nature which causes all disturbed bodies to gravitate, or vibrate until rest, equilibrium is restored. Literally we are vibrating to and fro, on a pendulum, and have fallen asleep. Some day science will stop our pendulum, and we will awake to discover, that in spite of our holly activity, we have really been sleeping. Science as well as common sense tells us that vice is ruinous to the mind and body. Religion rebukes us if we go astray. We laugh at both, and why? The truth is our prejudices are still deep-seated, and we are bound to have what we term pleasure. All this is the result of erroneous ideas imbibed perhaps in our youth, from a too constrained watchfulness. Science steps in and aids religion, while it has nothing whatever to do with it; but its aid is not that of violent denunciation, but the bringing into subjection to man's use and enjoyments all of the forces of nature. The workings of science are quiet and peaceful, unknown to the majority, but nevertheless effective, and will accomplish more than prohibitory laws ever can, and for the reason that they furnish him with all he requires or desires, and imposes no restrictions upon him. This is just what the heart of man desires in the present condition of the world, and when this shall be accurately known and understood, mankind will awake from an unreasoning sleep and be improved in health, morale and general intelligence.

THE BLESSING OF LABOR.—I believe that for most men more than eight hours' work per day is required for the maintenance of physical, mental, and moral health. I think that for most men including operatives, mechanics, farmers, and clergymen, more than eight hours' labor per day is necessary, in order to keep down and utilize the forces of the animal nature and passions. I believe that if improvements in machinery should discharge men from the necessity of laboring more than six hours a day, society would rot in measureless and fatal animalism. I have worked more than ten hours per day during most of my life, and believe it is best for us all to be compelled to work. It would be well, I think, if we could make it impossible for an idler to live on the face of the earth. Religious teachers are not without responsibility for having taught that the necessity of labor is a curse. The world owes most of its growth hitherto to men who tried to do as much work as they could. Its debt is small to the men who wished to do as little as possible.

—*June Atlantic.*

LOW WATER IN BOILER.—Whenever the water in a boiler becomes dangerously low, the attendant should immediately draw the fire and allow the boiler to cool. He should not admit any cold water to the boiler, or attempt to raise the safety valve, as this is a dangerous proceeding. It lessens the pressure by allowing the steam to escape from the boiler and thus permits the water to rise and come in contact with the overheated iron. Probably many explosions have been caused in this way.

MECHANICAL PROGRESS.

Steering Made Easy.

To avoid the slackening of rudder chains and the constant jerking of the rudder in a rough sea, Capt. Sam Martin, of New York, has hit upon a valuable invention. His plan is to cut out a certain section of each rudder chain about midships of the vessel, and in the place of the detached pieces put cylinders. In each cylinder he placed a piston, and connected the rudder chains with each piston. This done he had to all purpose the same old steering apparatus, for the pistons were simply links in the rudder chains, and could be moved by turning the wheel in the pilot-house. The next thing to do was to apply steam to the cylinders. They were consequently joined by a steam pipe, the boiler was tapped, and the steam supplied through a valve in the pipe connecting the two cylinders. This valve he operated from in the pilot-house. When the lever in the pilot-house was straight, it showed that there was an equal pressure on both pistons, and that there was as much steam in one cylinder as the other. As the lever was moved, and the rudder turned, it transferred a percentage of steam from one cylinder to the other, and as the piston of the right cylinder went in, the piston of the left proportionately ran out, taking up the slack chain at the stern and holding the rudder taut in any position. By turning the lever to a certain point both cylinders were exhausted and the steam shut off.

The wheel in the pilot-house not only served as an indicator, night and day, to show that the cylinders were answering the turn of the lever, but it could be used in another way. If there was a break in the machinery, or the steam ran low, the vessel could be steered in the old-fashioned way with a man at the wheel, the pistons in the cylinders acting as a link in the chain that leads from the wheel to the rudder. A practical experiment on the steamer *Maryland* from Jersey City to Harlem, satisfied every one that a boy of ten years could manage the helm.

The main point of Capt. Martin's invention is its cheapness. He says it can be put in any steam vessel for an eighth of the cost of any steam steering apparatus now in use, and the cost of the steam is a mere bagatelle. Those now in use are run by donkey engines, requiring the services of extra men at the engines. Capt. Martin gets his steam from the boilers in actual use, and dispenses with the services of men already employed.

SUBMARINE ENGINEERING.—Some very interesting experiments have lately been made in raising sunken vessels or other submerged objects by a plan invented by a Viennese engineer. The *Berlin Tribune* says that the agent employed to lift the sunken objects is carbonic acid gas, generated below the surface of the water. In an otherwise empty balloon a bottle of sulphuric acid is placed, embedded in a quantity of Buller's salts, and an arrangement is provided by which the bottle can be broken at pleasure. The balloon, empty, with the exception of the bottle and the salts, is taken down by a diver, and securely attached to the object to be raised. The bottle is then broken, and the sulphuric acid thus set free percolates the salts and generates carbonic acid gas, which inflates the balloon, and after a time, causes it to rise to the surface, bringing with it the object attached to it. The trials which have been made with this new apparatus have, as yet, been only on a comparatively small scale, but they are stated to have been, so far, eminently successful. A small vessel, weighing several hundred pounds weight, was sunk in 60 feet of water, a diver was sent down and attached the balloon to it, and in a very short time the machine appeared on the surface of the water, bringing the vessel with it. On another occasion five sacks filled with sand were thrown overboard in 50 feet of water, and in five minutes were similarly recovered.

PRINTING PRESS MARVEL.—It is a puzzle to the ordinary mind that an unbroken sheet of paper may be made long enough to stretch from St. Louis to Illinois Bluffs, seven miles away. But what can exceed the ingenuity that constructs a machine that with a push of a lever takes the snowy paper into its ponderous iron jaws, and with the speed of an express train, imprints upon it even the faintest hair line of the smallest type, divides it accurately and uniformly into pages, places it in a book form, glueing the backs, cuts the edges, and then folding these pages as evenly and smoothly as a girl would fold her first love letter, delivers the perfect newspaper—six, seven, eight, in one second!—*Missouri Republican*.

NARROW-GAUGE RAILWAYS.—Light railways with gauge varying from 18 to 24 inches can be advantageously employed in carrying on a large farm, a stone quarry and similar works. A London firm is making light railways a specialty, and from their circulars it appears that the entire material above the road bed for 10 miles of railway, with a locomotive and car, can be obtained for as little as \$2,500 to \$3,000. We fully believe that light railways of narrow gauge are eventually to take the place of horses and wagons to a considerable extent, not only for public but also for private purposes.

TIN PLATE MANUFACTURE.—The consumption of tin, or more properly tinned iron, costs this country every year nearly \$20,000,000, of which at least \$15,000,000 is for labor which ought to be paid to American workmen. Some progress has been made in this industry in New York city. The Monitor Tin Plate Company, of New York, occupies a building in Horatio street, where the tinning is done. The iron is rolled in Pittsburgh, Pa. The sheets are rolled in the ordinary way, then cut or sheared to size and immersed in a pickling bath. They are then cold-rolled again, annealed and pickled, and put into baths of Russian tallow or palm oil. Then they pass through several baths of tin melted at a high temperature and again through sawdust and bran to cleanse the surface. Finally they are polished with lamb's-wool buffers and assorted, ready for boxing or shipping. This is the old method of tinning by hand that has been in vogue in Europe for the last hundred years. We believe that the same results can be accomplished by the use of machinery, in which case the tinning will be greatly accelerated, and the cost of tin much decreased. The business has assumed such importance that the late convention of iron and steel manufacturers held at Pittsburgh sent a petition to Congress suggesting a change in the law imposing duties on tin, stating that the tin plate business represents an annual consumption of over 150,000 tons of pig iron, about 1,000,000 tons of coal, and about 50 rolling mills having two trains each, all required to supply the demand for that article, and that protective duties should be imposed to develop this industry which would give employment to at least 40,000 persons.

SPIDERS KILLING TROUT.—Seth Green, the noted pisciculturist, has been for a long time puzzled by the terrible destruction of very small trout, and his investigations have at length resulted as follows: "There is a small worm which is a favorite food of trout and many other kinds of fish. This worm is one of the greatest enemies which the young fry have. It spins a web in the water to catch young fish, just as a spider does on land to catch flies. I have seen them make the web and take the fish. The web is as perfect as that of the spider, and as much mechanical ingenuity is displayed in its construction. It is made as quickly and in the same way as a spider's, by fastening the threads at different points, and going back and forth until the web is finished. The threads are not strong enough to hold the young trout after the umbilical sac is absorbed, but the web will stick to the fins and get around the head and gills, and soon kills the fish. I have often seen it on the young trout, and it has been a great mystery and caused me many hours, days and weeks of wonder to find out what was wound around the heads and fins of my young trout and killed them. I did not find out until lately, while watching recently-batched whitefish. These are much smaller than the trout when they begin to swim, and they were caught and held by the web. I found ten small whitefish caught in one web in one night. The web was spun in a little whitefish preserve into which I had put 100 young fish."

A NEW ROAD LOCOMOTIVE.—A new road locomotive has lately been patented by Richards & Dale, 36 Taylor street, Springfield, Mass., in which the traction will be secured by vertical bars acting as feet, dispensing entirely with driving wheels. The motive power will be applied directly to the main shaft by a crank-rod and crank, as in ordinary engines. No new principles being thus involved in the use of the steam, the machine is very simple and more likely to be practicable. The frame of the engine is horizontal with a two-wheeled truck at the rear end, while the main shaft is in front, in a horizontal transverse position. This shaft hears four cranks in addition to those that drive it. Upon each of them is a leg consisting of a straight bar, provided at the lower end with a suitable foot or shoe by which the traction is obtained. There is also an arrangement for shortening the length of the step in ascending grades or drawing unusual loads. The machine will work equally well backward or forward, and if a foot should happen to cut a channel in the ground without drawing the carriage forward it can be turned in either direction to get a fresh start. The engine may be detached from the feet so that it can be used for hoisting as well as locomotion. In the absence of illustrations we are unable to say whether the machine could be made serviceable in our mining regions or not.

IMPROVEMENT IN CHANDELIERS.—A patent has been taken out by a Philadelphia inventor for a sliding chandelier, which has none of the dangerous and cumbrous mechanism of hydraulic pulleys, chains and weights now in common use. The apparatus consists of a cylindrical chamber, about two inches in height and one and a half inches in diameter, closed at top and bottom. Within this is a dual spring; a brass band slotted down the surface, rimmed at the top and turned at the base, being encircled by a coiled spring, the two contracting and expanding automatically. Within the band, and filling up the space which surrounds the sliding rod, passing through the chamber, are a number of perfectly rounded and smooth metallic marbles, and these, together with the double spring, firmly grip the sliding rod, which can be drawn down or pushed up with freedom and certainty, and without the possibility of the rods slipping, or the apparatus getting out of order.

SCIENTIFIC PROGRESS.

THE WORLD IN WAX.—Mr. Grube, a maker of wax images in New York city, has constructed what is claimed to be the largest globe of the world, showing the ranges of mountains and other peculiarities of the surface of the earth, in relief, now in existence. Its diameter is four feet and about one inch, the scale being one in 10,000,000. The range of even the Himalayas would not be visible upon this globe if the scale were adopted for the elevations as for the map, and accordingly the relief is made upon a scale which exaggerates heights twenty times. The oceans, seas and rivers are colored blue; the continents are yellow; the glaciers, icebergs and floating cakes of ice white. Plains and mountain ranges are clearly shown, and every part of the world is exhibited in its true character. Red, black and white lines cross the globe to indicate the isothermal belts, the variations of the magnetic needle, the data line where ships correct their logs by skipping from Saturday to Monday, and vice versa, and other facts of like character. The map has been corrected in the light of the latest discoveries down to two months ago. The northern coast of Siberia has been much altered in the atlases by the Nordenskjöld expedition, the ships sailing in deep water over places marked as 500 miles inland, and being compelled to go hundreds of miles around promontories, etc., which are occupied on the maps by bodies of water. The globe is made of wood. The relief is formed by wax. Mr. Grube has been two years in perfecting his globe, and Chief Justice Daly and other geographers have lately been giving attention to it.

NEW ANTISEPTIC SALT.—During some experiments in separating sugar from molasses, a double salt of borate of potassium and sodium was found, that proved to have valuable antiseptic properties. This salt is now manufactured on a commercial scale, and costs about 10 cents a kilogramme or five cents a pound. It is obtained by dissolving in water equal quantities of chloride of potassium, nitrate of sodium and boric acid, filtering and evaporating to dryness. The salt is said to be quite deliquescent, and must be kept in tight bottles. It is quick in action, retains its qualities for a long time and has no injurious effect upon the taste, smell or healthfulness of the substances to which it is applied. It has already found a use in making sausages, in preserving meats, in tanning and in butter-making. A small quantity of the salt added to milk will preserve it in good condition for a week. It is also used in preserving beers and wines, and is being made the subject of experiments in several other directions.

INDIAN STEEL.—The remarkable metal known as *wool*, or Indian steel, is now imitated with considerable success in some of the workshops of Europe, the process being as follows: Small pieces of very good forged iron or steel are put in a crucible and covered with charcoal; air is carefully excluded, and the mass exposed to heat until it turns dark gray—carbureted of iron, this is easily pulverized, and in this state it is mixed with alumina and subjected for a long time to a white heat in a crucible, when it becomes white and brittle. If 1-16 to 1-12 of this white mixture is melted with some good steel, a very good imitation of Indian steel is said to be the result. Commercially speaking, the genuine raw steel, or *wool*, comes in three forms, namely: in bullet-shaped pieces of certain weight, as they cool in the pots, and which comes from Calcutta; in cakes of two and a half pounds, from Bombay; and in cylindrical rods of about the same weight, from Golconda.

CHINESE PORCELAIN.—The Chinese subject the greater part of their porcelain to but one firing, first drying the pieces sufficiently in the air to prepare them for glazing. This plan they are able to pursue, because the nature of the material is such that it resists the entrance of water. Their glaze is much superior to any in use in the European potteries, but it requires the most intense degree of heat for its fusion, and considerable art is consequently required for the management of the fire, as well as in the construction of their ovens. These are built in the most substantial manner, so that when the fire is at its greatest height the band may be applied to the outside without any fear of burning.

TOUGH OLD IRON.—Two specimens of old iron, made some 60 years ago, were recently taken from a bridge in Baltimore and tested, with the following results: Specimen No. 1, (wrought iron) 11 15-16 inches in length, elongated to 12 9-16, broke at a strain equal to 52,836 pounds. Specimen No. 2, length, 10 1/2 inches, elongated to 12 1/2 inches, broke at a pressure of 61,880 pounds. The bolts were placed in the bridge when it was built, 60 years ago. It may well be queried whether any great advance has been made in the manufacture of iron as to quality, in the time that has elapsed since those specimens were made and placed in that bridge.

NEW DYE.—Sulphoamidazoehenzolic and sulphoamidazotoluolic acids have been made permanent canary and orange yellow dyes by the conjugation of the sulpho-acids with amidazoehenzol and amidazotoluol, the excess of acid neutralized by dissolution in alkali and concentrated. The colors are dyed in a slightly acid bath.

COATING IRON WITH IRIDESCENT COPPER.—A writer in the London *Mining Journal* thinks the invention of Dr. Weil, of Paris, for coating iron and steel with copper or nickel in such a manner that the surfaces shall be iridescent, opens a large field for the employment of metal for decorative purposes. He has found that the best mode of preparing the metalizing bath and the best proportions of ingredients are indicated in the following directions: First, 35 parts of crystallized sulphate, or an equivalent amount of any other salt of copper, are precipitated as hydrated oxide by means of caustic soda or some other suitable alkaline base; this oxide of copper is to be added to a solution of 150 parts of Rochelle salt, and dissolved in 1,000 parts of water; to this 60 parts of best caustic soda, containing about 70% NaO, is to be added, when a clear solution of copper will be formed. All colors, from that of brass to bronze, scarlet, blue and green may be produced at will. A Gramme machine may be substituted for the alkaline bath. The ornamental iron castings made both in Great Britain and France are really beautiful in form and design, and by the judicious coloration of them with combinations of iridescent brass and scarlet, brass and blue, or brass and green, would produce effects which would insure their general adoption.

THE SPECTROSCOPE AND HIGH TEMPERATURE. The employment of the spectroscope in the comparative measurement of high temperatures has been described by M. Crova, of Montpellier, France, before the Académie des Sciences. According to his description, this instrument can be employed to measure temperature hitherto incalculable. The process which he recommends is thus described: Having first adopted some arbitrary standard, he proceeds to examine the flames of incandescent bodies with the instrument, and reduces them, by the interposition of obstructives of known value, to the same level as that of the standard. To this combination of devices he applies the name of spectrophotometer. Prof. Crova adopts as his standard the heat emitted by an ordinary moderator lamp burning oil, which he fixes at 1,000°. In making his comparisons, he finds the heat of a piece of platinum heated to redness to be 524°; the same at white heat, 810°; a regulation stearine candle, 1,162°; an Argand burner of common coal gas, 1,373°; lime light, oxygen, and coal gas on line, 1,806°; the electric light, 60 Bunsen elements, 3,060°; and the light of the sun, 4,049°.

POSITION OF THE PLANETS FOR JULY.—Mercury can be seen after sunset all through the month of July. Early in the month it keeps nearly the path of the sun; later it moves south of the point of sunset. On July 20th, it may be seen east of the crescent moon. Venus, on July 8th, passes near to the planet Uranus, but moves rapidly toward the east. It will be near the crescent moon July 22d. Mars, Saturn and Jupiter can all be seen at a late hour in the evenings of July, about midnight. Jupiter will be known by its size and brilliancy, Saturn by its white light, and Mars by its ruddy glow. Uranus may be found with an ordinary glass by its nearness to Venus. On July 8th, Uranus is a little south of Venus, after that it will be found west of Venus and a little north.

SELENIUM CAMERA.—The *Scientific American* refers to some very ingenious and curious applications of selenium, in which its peculiar property of changing its electrical conductivity when exposed to light varying in intensity, is utilized. The several devices are the invention of Mr. George R. Carey, of Boston, Mass. Perhaps the most curious of these instruments is the selenium camera obscura, which is capable of transmitting, telegraphically, an image of any object and making a permanent impression of it at a distant point. In this case a person may sit before the camera in New York while his photograph is made in Boston.

COLOR OF THE ELECTRIC LIGHT.—By the combination of the suitable chemicals during the manufacture of the carbons, or by saturation afterward, almost any colored tint may be obtained. The natural violet rays are neutralized by the addition of a few grains in each carbon of chloride of sodium, producing a yellow tint like the sunlight. Magnesia produces a very white light, and is well adapted to photography. A mixture of arsenic, on the contrary, produces a light almost devoid of chemical effect. Various proto-salts and sulphates of the metals may be so combined as to produce almost any desired color.

POLARIZED LIGHT IN GASES.—The rotation of the plane of polarized light in gases has just been effected by two German experimenters, MM. Kundt and Rontgen, with the aid of powerful electro-magnets, made by passing the current from 64 Bunsen cells through six coils of thick wire (each comprising 400 turns) surrounding a tubular iron core. They showed that saturated vapor of carbon bisulphide at 100° C. rotates the plane of polarization of light in the magnetic field produced by this electro-magnet.

TRANSMISSION OF POWER BY ELECTRICITY.—Prof. Houston and Thomson have experimentally shown, at the Franklin Institute, that powerful electric currents can be conducted by very fine wires. They sent the current generated by one dynamo-electric machine through a wire .004 inch in diameter to a second machine, which, working reversely, gave off considerable power.

The Mining Share Market.

The local market for mining shares continues weak and wobbling, a condition that may justly be pronounced unsatisfactory all round. Indeed, the business seems, just now, sadly demoralized, what, with the total suspension of dividends on the Comstock, the tardy developments at expectant points and the low grade of the ore now being raised from the few producing mines left on the great Washoe lode, having overwhelmed with disappointment the whole army of dealers, leaving all in doubt as to what will come next. The benefits to accrue from the completion of the Sutro tunnel had been discounted so far in advance that their effect is no longer felt. The find in Union Con. having shrunk on its first dimensions, the output from Sierra Nevada continuing restricted and the Bonanza ores tending to a lower grade, nothing else than stagnation and gloom could be looked for; the more, that money with this many is tight, politics rage and times are far from promising. No wonder then the mining share market is lifeless, prices depressed, "and the mourners go about the streets." The recent spurt in Alta has already subsided—was brilliant but overcast, going up, like the Fourth of July rocket, a blazing meteor and coming down a blackened stick. Even the much-talked-of stir in the New York mining share market does not appear to blaze up according to expectation. The thing sizzles and spits, but fails to ascend with those glorious convulsions that so gladden the stock dealer's heart. In this untoward state of things there is this consolation: What the manipulators fail to make the masses fail to lose, showing how largely the compensating principle enters into the affairs of human life. But the manipulator is not discouraged. He knows well the habit of these dabblers in stocks, and that, after a brief season of financial recuperation, they will return to the gamble, affording him a chance to clean them out in the end.

An Important Decision.

The Secretary of the Interior has announced a decision reversing the decision of the Commissioner of the General Land Office in the case of the Iowa mining company versus the Bonanza mining company of Nevada, and laying down a new principle of great importance in mining controversies. The Bonanza company, in January, 1876, made application for 593 feet of the Lucky Baldwin lode. The Iowa company holding an adverse claim, commenced suit thereon in April, 1876, by filing a complaint in the First District Court of Nevada, and causing summons to be issued. It was shown, however, that as late as May 24th, 1878, service had not been perfected on the defendant, and that no further steps had been taken by the plaintiff in the prosecution of said suit. The General Land Office, on this state of facts, decided, last October, that the Iowa company had waived its adverse claim by failure to prosecute said suit with reasonable diligence, and that the Bonanza company was therefore entitled to receive a patent as soon as the ordinary requirements of the mining law should be complied with.

Secretary Schurz, reviewing this decision, says: "Section 2326 of the revised statutes provides in plain terms that a failure on the part of an adverse claimant to prosecute his suit to judgment with reasonable diligence, shall be a waiver of his claim, but it does not provide either in terms or necessary implication that the General Land Office shall decide what constitutes 'reasonable diligence' while the suit is pending in Court. The object of this law clearly was to require parties claiming an adverse interest in land included in an application for patent, to try the right of possession and have the controversy determined by the State Courts before any issuance of a patent. The question of diligence in the prosecution of a pending suit is as much a question for the determination of the Court as any other question of law or fact which may arise in the progress of the case, and one which, after the Court has acquired jurisdiction, should be left for its determination."

The Secretary points out that otherwise the General Land Office might hold that reasonable diligences had not been exercised, and issue a patent, while the Court might give judgment for the adverse claimant, thereby producing conflict of authority and confusion of titles, and, as a consequence, further expensive litigation, etc. He therefore says:

"I am of opinion that the proper practice in cases of this character is for the defendant, if, in his opinion, the suit is not prosecuted with reasonable diligence, to move the Court to dismiss the case for want of prosecution, and if the motion is granted, cause the judgment to be certified to the General Land Office, when a patent can be issued without conflict with the jurisdiction of Courts or the rights of parties in interest."

The *Jeannette* Bennett's Polar steamer left on her voyage Tuesday, July 8th, escorted to the ocean by the yacht fleet and numerous tugs—receiving from the fort a salute. She will float on the Japanese and Polar currents from Behring's strait to Davis strait.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ITEMS.—*Dispatch*, July 5: The miners on Mule creek are said to be complaining of the scarcity of water for mining purposes in that locality. We learn that the first haul of 500 tons of ore, taken from their mine above Volcano, crushed at Mule's mill last week, which yielded the net little sum of \$2,600, or an average of about \$50 per ton. The new hoisting works at the Butte Basin mine, at Butte City, have been completed, and will be put in active operation next Monday. The machinery will be run by water power. A fresh body of good rock was struck in the Onida mine a few days ago. The ledge was struck in the lower drift. The shaft of the Moore mine is being widened.

BUTTE.

ARMSTRONG MINE.—*Mercury*, July 4: This property is located about three miles south of Boston ranch. A company of 500 men, purchased the ledge about three months since, and have had three men at work ever since opening the mine. One tunnel has been run in a distance of 100 ft, and work was begun on another one last Friday. Thus far the assays of the rock have been very satisfactory, and it is very likely that a mill will be put in operation before the fall.

JOHN C. LEEVER TUNNEL.—The Sunnyside mine, situated near the Colyer mine, made a big clean-up a few days ago, the rock averaging \$60 per ton.

INYO.

MOORE CON.—*Independent*, June 28: Progress on the 1000 level for the week ending June 24th, is as follows: Tunnel run 48 ft; total length, 1,784 ft. Drift, 536 ft; run 4 ft; total length, 109 ft. Drift, 1,000 ft; run 8 ft; total length, 67 ft. Drift, 1,109 ft; run 17 ft; total length, 50 ft. Face of main tunnel is in good ground, with some manganese and crystalline lime in face.

MINNETTATA.—The Minnettata mine, at Lookout, now the property of Messrs. Belshaw & Baudey, is likely to be tried up on the several hundred tons of tailings from old workings. George Center, of Eureka, has lately been over there making assays. The last run on Minnettata ore at the New Coso furnace, about 60 tons, resulted in a yield of between \$6,000 and \$7,000.

THE UNCLE ABE.—We have heard but little about this mine for some time past, but the owners, Dodge & Hitchcock, have not been living quiet by any means. They have a drift on the level in a distance of 300 ft, and have now exposed, to the view of any one who desires to go and see it, a streak of splendid ore, showing without a break for a depth of 170 ft. This ore carries considerable base, and it is likely a hundred tons or so of it will be brought to the Rex Montis mill for reduction.

SILVER PEAK.—From A. J. or "Jeff" Davis, who is just in from Silver Peak, we learn that the old camp is steadily progressing. Superintendent Bronson has been running the mill upon some 200 tons of gold ore, with fine results. A force of eight or ten men is being worked at the company's old silver mines, and a smaller number on the gold ledges. The company are about putting up a new mill at Gold Springs, about seven miles from the present one.

A PATINO MINE.—Messrs. Cardes, Meier and Schroeder have been operating upon a little mine in Alabama district for some time past, and are doing it very well. They do everything within themselves, using an arrastra for reducing their ores. Their second clean-up for this month yielded 43.63 ounces gold, worth \$13.50 an ounce, making \$575.50 in all. Their shaft is down about 40 ft. They are favored in the peculiarity that they have never yet had to put in a single blast, the pick and sledge being all sufficient without powder.

MONO.

ITEMS.—*Standard*, July 3: A tunnel has been run in the first location of the True Blue 300 ft, into a solid mass of ore. The surface ore assays \$10 per ton. The True Blue tunnel site is located 1,200 ft southerly and 2,000 ft from the proposed Mammoth tunnel. The ledge dips in the direction of the proposed tunnels. In the Noonday ledge, as far as explored, holds out quite regularly and satisfactorily from three to five ft in width and of \$20 to \$35 ore. The ore carries gold chiefly, and has that general lively appearance characteristic of the big ledge now attracting so much attention in the Standard ground.

INDIAN QUEN MINE.—During the past year, over 2,500 linear ft have been driven on the fissure, in the extension of tunnels, winzes and crosscuts. In making these developments, 1,300 tons of ore have been extracted and milled, the assay value of which has averaged about \$120 per ton, making the gross value of the ore \$157,360. The haul shipments aggregate about \$150,000, showing a working of the ores up to 95%. Prospecting will be confined to tunnel No. 5, which has been extended 150 ft on the vein.

THE ONEOTA.—This mine is located about half a mile north of the Indian Queen, and on the same fissure. The company is now running a 400-ft tunnel to tap the vein. This tunnel has now about 80 ft to go to intersect the old body. The owners of many adjoining claims are awaiting the issue of the Oneota, and should a bonanza be developed, work on them will be pushed vigorously, and perhaps another Chinese excitement inaugurated.

ITEMS.—*Bodie Chronicle*, July 6: Some time ago the Sandbar claim located Silver Hill, directly east from the Noonday, was bonded to Jeremiah Miller, President of the South Bulwer company here. We are informed by the owners of the property that it has been sold to San Francisco parties and the money paid. This mine has been opened by an incline shaft run down on the vein, disclosing a fine body of quartz, bearing ore of considerable richness and extending as far as developed.

UNIVERSITY.—East crosscut on 2d level is in 150 ft, formation hard porphyry, carrying seams of clay. South drift is in 63 ft in fine quartz.

RITCHIE.—East drift on 250 level is in 03 ft; west drift, 20 ft. The work is in fair ground.

MONO.—A new set of timbers is being placed in main shaft.

NOODAY.—North drift on 200 level is in good milling ore. Winze on 300 level is down 10 ft in a three-ft ledge assaying \$90.

SOUTH BODIE.—East crosscut now in 150 ft from main shaft at the 500 level.

NORTH STANDARD.—Several small stringers of quartz prospecting well in gold are met in the double-compartment shaft.

WENDEN.—West crosscut from north drift is in 32 ft. South drift, 400 level, has advanced from main shaft 132 ft. A small flow of water coming in on face of south drift.

ROUGH AND READY.—Shaft down 16 ft in ledge two ft wide, assaying \$60. Drifting on ledge will be commenced at a depth of 300 ft.

McKENNA.—The mine has forced the men out of lower level. Work is concentrated on 500 level and new shaft 700 ft to be sunk.

ITEMS.—*Bodie Chronicle*: A 30-stamp mill is in process of erection by Malter & Lind, of San Francisco, for the Noonday and North Noonday mining companies. The engines are Corliss. The Standard, Bulwer and Bodie have millions at sight. The extreme workings of the Bodie, as to depth, were hampered by water for a few days, but a cheap pumping apparatus was obtained from Aurora and work of sinking deeper resumed on Thursday. The extreme bottom of winze on lower level was never looking better. Tioga and Jupiter are pushing down their main shafts as rapidly as possible; ditto Noonday, and all are drifting and extending as usual. Mono is also sinking main shaft with lightning speed, running the east joint crosscut accordingly, the formation being most favorable for obtaining a slice of the Bodie bonanza. The Syndicate will soon have connection completed between

the mill, tunnel and ledges, and be independent of other companies' ores. The Bodie is sinking up rich ore in considerable quantities and is only waiting the arrival of steam pumps to resume sinking the main shaft. Con. Pacific will soon be sinking their main shaft with steam power. The Standard is rushing up the big pump, so that crosscutting on the 700 level can be resumed, and also sinking main shaft to greater depths. The Booker will get up steam most any day now and have their big pump running preparatory to their full capacity, and two new mills are projected. The first bar of bullion from the Standard was shipped in April, 1877, and from that time down to June 25th, 1879, the mine produced and shipped \$2,366,771, of which \$1,300,000 was paid over to stockholders in dividends. It is said there is enough ore in sight to keep the mill in operation for two years more. The first bar from the Bodie mine was shipped in July, 1878, and from that time down to June 25th, 1879, the mine has produced \$1,242,712, and paid \$900,000 in dividends to stockholders. This mine has recently renewed its lease of bullion-bearing rock, and bids fair to yield handsomely for some time. It is said that Mono county has given \$4,000,000 to the world since the renewal of operations at that camp in April, 1878.

NEVADA.

ITEMS.—*Foothill Tidings*, July 5: The Round Mountain company have struck large builders, and are near the main channel. The Derbec has about 1,000 tons of good bullion ore on the dump.

NEW YORK HILL.—*Grass Valley Union*, July 2: Ford, Mullen & Co. have of late been sinking a new shaft on the McDonald & Mullen ground, on New York hill, and on Saturday last, at the depth of 90 ft, they struck a stringer of very rich quartz, scarcely a piece of which but shows finely in free gold. The boys regard the strike as a valuable one, and from the appearance of the rock taken out, they have good reason for that opinion. In the old workings of this claim, tributaries are still at work, and taking out good pay rock.

CENTRAL MINE.—Amount of ore raised and crushed at the Orleans mill, from this mine, has been 500 loads, the yield of which and sulphurets (and specimen sold for \$20) amounted to \$24,928.20, an average of \$50.20 per load, which is considerably better than the average of last year.

ITEMS.—*Frontier*, July 5: The mine developed at the Excelsior mine at Smartsville was over \$90,000. Ground is being broken at the Murchie mine to put in four new Frue concentrators. The four that have been in use there for several weeks past do their work so well that the company will discard the use of the Hendy machines altogether. Adolph Chaty, employed at the Derbec, came down the other day to secure the last of his mining work in the mine. About 50 men are already working underground in the claim, and the new ones are wanted to increase the force. Additions will be made to the force as rapidly as room can be made for them. Drifts Nos. 7 and 8 have been connected. The gravel at this point is about 100 ft wide and is very rich. The monthly clean-ups are now being made at a number of mines in various parts of the county.

ITEMS.—*Frontier*, July 5: About 1,000 tons of good looking gravel is on the dump at the Derbec mine. The Idaho mining company has declared a dividend of \$5 per share for the month of June. About 1,000 tons of good looking gravel is on the dump at the Derbec mine.

JORNOS.—*Herald*, July 3: Work in the El Capitan continues to develop good ore. The lead at the head of the 1st level is from two to three ft thick, and shows some free gold and much sulphurets. Indications are good for a first-class mine. The Deadwood company has lately struck a bonanza of ore that is very rich, and the fault could reasonably be found with that previously extracted. The prospects of the Deadwood making a first-class mine, grow brighter every day. Their shaft will reach the 3d level in 30 ft more. The Eureka Lake and Yuba Canal Co. cleaned up after a small run of two weeks in the Chimney Hill and Farrell claims, which resulted in over \$17,000.

PLUMAS.

ITEMS.—*National*, July 5: At the Gold Stripe mine the 24 large stamps crush from 35 to 40 tons of rock every 24 hours. The rock averages \$9 per ton. The ore in the mine and in the neighboring ones exists in very large quantities. The Miner vein at the head of the mine is quartz, in many places filled with rich sulphurets and about 3 to 4 ft in width. The tunnel is 900 ft, large and well timbered. In the Plumas National mine the ledge shows well in the shaft, five or six ft thick and the quartz bristling with sulphurets. The lower tunnel was driven 900 ft to the ledge.

TUOLUMNE.

A GOOD FIND.—Robert Sloan, an old American Camp miner has had the good fortune to strike a big lick in quartz. Last week, in prospecting half way up the ridge, near Five Mile creek, he discovered an exceedingly rich quartz lode. The ore is small as it crops out of ground, but the 40 or 50 pounds he broke off are nearly half gold in weight. The ore is so rich that it flattens out in the mortar, when pounded, like lead. Should the vein prove as rich below the surface, at any depth, he has all the wealth he can wish for.

YUBA.

ITEMS.—*Appeal*, July 2: From the recent rich washing of gravel in the Nevada and Golden Oate hydraulic mine, at Sucker flat, in this county, about \$900,000 in the aggregate have been taken out from a comparatively small amount of ground as yet assayed over. But Campbell, the superintendent of the mine, conceived the idea to sink bedrock cuts, with lateral branch tunnels opening into the main channel, with the result above stated. It is said by old miners and those who have seen it, that the gravel is literally bespangled with gold.

NEVADA.

WASHOE DISTRICT.

OHRA.—*Gold Hill News*, July 10: On the 2000 level the upraise from the south drift has been connected with the sixth floor of the stope and materially aids ventilation. The drain-pipe to the Sutro tunnel is laid, but all the connections are not yet made.

OVERMAN.—At the Forman shaft both stations are being cut at the 300 and 600 levels. The timbers of the shaft are being eased in places. The shaft has attained a depth of 755 ft. A hoisting engine is being put in at the head of the winze from the 1600 to the 1900 level, which will cause a suspension of the work of sinking for two or three days. The pipes in the mine have all been connected with the Caledonia tanks, and yesterday morning the pumping engine was uncoupled, preparatory to removing it to the Forman shaft.

NORTH BONANZA AND FLOWERY.—The station on the 400 level has been completed and the cluto is being timbered. When this is completed, sinking will be resumed and the lateral drifts above started up again. The north lateral drift on the 300 level is making rapid progress along inside the vein, and is cutting quartz which continues to improve as the drift goes on.

ALTA.—On the 1550 level the ore body has been opened by crosscut to the east wall and found to contain 12 ft wide of good ore, most of which is very rich, and two feet more of low-grade ore lying next to the clay.

CON. VIRGINIA.—The joint west drift, 850 level, is cutting a vein formation showing some quartz, its face 420 ft in.

JUSTICE.—The stope on the 950 level are yielding a small amount of good ore. Crosscut west, on the 1550 level, has just cut the clay wall of the ledge, showing some very nice looking quartz to the west, but has not yet penetrated the ore body far enough to prospect it. The crosscut east on the same level is in very favorable formation, with seams of ore assaying very well. The main lateral drift south on this level is in favorable vein matter.

CHOLLAR-NORCROSS-SAVAGE SHAFT.—The work of pump-

ing into the Sutro tunnel goes on favorably. As the water is lowered it is found that in places the heated flood has swelled the timbers somewhat, so as to render it necessary to ease them. By the first of the week the pumps will be ready to take water from the flooded mines through the "lightning drift" and raise it also to the tunnel level.

BULLION.—The bulkheads put in at the time of the fire in the Imperial have been all removed, and the mine found to be uninjured with the exception of the destruction of four sets of timbers on the 2000 level. The workings are being cleaned up, preparatory to the resumption of operations. This will be done the last of the week.

SAVAGE.—The work of pumping into the Sutro tunnel is going on vigorously. The 2000 has been cleared, and found to be uninjured. It is expected that the Chollar-Norcross-Savage shaft will be ready soon to take water from the mine, when donkey pumps will be set at work, and about as much water will be sent over there to be raised to the tunnel level as is now being sent directly to the tunnel. This will greatly aid in clearing the lower levels.

ENCINER.—The bulkhead placed in the north drift, 2400 level, at the time of the fire in the Imperial, has been removed. The mine has sustained no damage, and as soon as an engine and hoister can be placed to furnish air to the drift, work will be resumed, although there is a fire, and hence the necessity of providing other ventilation and means of getting air into the drift.

SIERRA NEVADA.—Work in the mine has been interrupted of late by water from the west end of the old south crosscut, 2400 level. The flow is, however, decreasing and is readily handled, so the work can go again as usual, and stopping will soon be resumed, although there is an abundance of ore at the Mariposa mill for a month's steady run. The snub below the 2400 level is completed, as is also the 2300 station.

CALIFORNIA.—The joint west drift is averaging five ft per day through vein matter carrying some quartz; total level, 2400 ft. The tank at the 1650 level of the C. & C. shaft is in place, and the pipes connected with it preparatory to taking water to the Sutro tunnel, but all connections beyond have not been completed.

LEVATHAN.—Some improvement has been noticeable during the week, in the face of the north lateral drift on the 750 level, more quartz coming in with better assays. The 1000 level, Fair progress has been made in sinking the winze below the 1500 level, and a fine body of quartz of low grade is being developed.

LADY BRAYS.—On the 600 level the north drift is cutting a formation of broken quartz and porphyry, the former giving low assays. The south drift, same level, is also in low-grade quartz. The east drift, 750 level, is in birdseye porphyry and the west drift the same. Work at all points is making good progress.

BEST & BRACHER.—The east drift, 1700 level, is advancing through moist ground composed of clay and porphyry, and is making good progress. The Osbiston shaft is down 655 ft. Preparations for machinery on the surface are going on rapidly.

ANDES.—The crosscut east from the top of the raise and 60 ft above the 300 level is in fine looking vein matter. The crosscut west, 300 level, is developing some fine looking quartz, but of low grade.

BELMONT DISTRICT.

BELMONT.—*Courier*, July 5: Crosscut west from winz has been advanced 22 ft; will have about 10 ft further to run in cutting the ledge. The raise from 300 level was advanced 27 ft in a three-foot vein of quartz and slate mixed. The quartz is carrying a little nice ore all the way up, and when the vein becomes solid will find ore in paying quantities. Also crosscutting west from 400 level drift 100 ft north of shaft in which continuation of the ore body below 200 level, is expected to be struck.

WILLOW CREEK DISTRICT.

ITEMS.—*Paradise Reporter*, July 5: The Ekan Allen ledge is widening but improving in richness as work progresses. The Ohio is also improving. The shaft is down 25 ft, and very rich ore being taken out; 10 tons of rock now on the dump ready for shipment to Salt Lake for reduction. The ore vein on the Caledonia is three ft wide and very rich. A tunnel on the claim is in 25 ft.

JEFFERSON DISTRICT.

GOOD LOCALITY.—*Courier*, July 5: Some miners working in Jefferson canyon have struck rich ore, and the indications are favorable for finding it in large quantities. Jefferson district is one of the finest mining districts in Nye county, but for some reason or other the mines are allowed to remain idle. Enough good ore (with proper management and a judicious outlay of capital) could be extracted from some of the mines to keep both quartz mills in the canyon pounding constantly.

COLORADO.

LEADVILLE.—*Denver Tribune*, July 2: The recent strike in the Highland Chief is believed to be equal to the richest discoveries yet made. This property lies about three miles east of the Pittsburgh, on what is known as Breese hill, and but a short distance from the celebrated Breese mines. In the immediate vicinity are the Highland Chief, Black Prince and Miner Boy, all of which have mined in greater or less quantities. The Highland Chief shaft is 110 ft deep, and the body of mineral thus far developed is about 10 ft in thickness, and very rich. The Black Prince, situated a few hundred ft to the north of the Chief, and nearly 100 ft in a vertical line further down the side of the hill, came upon a body of mineral several weeks since, but of low grade. This mine was bonded for \$75,000, but before the bond was expired, the entire shaft caved in, leaving nothing behind but a small crater-like hole, about 12 ft deep and 15 ft in diameter. The Miner Boy, immediately adjoining the Black Prince, has recently come upon a body of low-grade mineral, probably the same that the latter struck several weeks since, and is now reported sold for the enormous sum of \$75,000.

CENTRAL DISTRICT.—Only one well-defined vein has been discovered as yet at Lump gulch, in Central district, the majority of the locations not yet having passed through the float to bedrock. One of the most promising, shows fine globules of silver when roasted in a blacksmith's forge. A large dyke of porphyry, east and west in its course, passes through this vicinity. Northeast of Ellisworth, Peterson & Co. have a well-defined vein of silver-bearing ore, which they have named the Bluebird, the ore carrying quite an amount of carbonates of copper. Owing to the heavy seepage of water, no work is being done on the lode at present. On the divide between Lump gulch and the old Froggett ranch, J. W. Brown & Co. have a shaft down to a depth of 15 ft. The ore assays from 40 to 180 ounces a ton, selected samples going much higher.

IDAHO.

IDAHO CITY.—*World*, July 1: Mr. R. A. Goodliffe discovered a free gold-bearing mine seven or eight miles east of town two or three days ago. He considers it a good ledge. He returned yesterday, accompanied by Mr. Ralph Calderwood. Mr. Goodliffe also discovered a base metal ledge, but he has not had any assays made of the rock. Mr. Dave Bunch has located a large mine near the head of Alder Creek, between the Highland Chief and the Bluebird, which is 11 ft wide and a four-inch streak in it is very rich. Mr. Louis Limbeck has a location on the same ledge.

YANKEE FORK.—*Personal*: The excitement has entirely subsided. But little work is being done on any of the mines, save the Norton, which has a tunnel 450 ft deep, in good ore, and a shaft 65 ft deep. Not over 40 men are employed in all the mines.

MONTANA.

BUTTE COUNTY.—*Times*, July 1: The Leggett Boy mine is finished and ready to make its first run as soon as the river recedes from the great rise of the past two weeks. The low ground bordering the river being overflowed, the roads are at present impassable, and will remain so while the freshest lasts. A spur starting from

Ornamental Cottage.

We give on this page a design by J. H. Hobbs & Sons, of Philadelphia, which may please some of our readers, who enjoy the ornamental in house building. Although this design inclines toward the elaborate and the ornate in the style of its finish, there is nothing excessive or not in keeping with the general plan. It is well adapted for a suburban or village cottage, rather than for a more strictly rural situation. Its form gives the exterior a variety of outlines which would distinguish it from most village houses as they are commonly designed.

By reference to the ground plan it will be seen that it is arranged for comfort and convenience. There is no waste room. The three principal rooms open directly into the front hall, which being room-like and large in its dimensions gives the impression of spaciousness to one entering the house. There is also a fine stairway upon one side of the hall. Attached to the kitchen, there is a large store-room, also a pantry. There can be a back stairway arranged between the dining-room and kitchen, if desired.

The second story, not shown in the engravings, is intended to be divided into four large chambers, each having a fireplace and clothes press. All the rooms are free and have separate entrances to the upper hall.

Concerning painting a house with such a varied outline and uneven surface, the architects write us as follows: "The paint should be only of one color, and trust to nature by the force of shade, sunshine and reflection to gild, darken and playfully light up and tint the various parts, which she does with far more delicacy than the patchy red blues and other striped colors, we so often see disfiguring otherwise good and beautiful designs."

It should be remembered when the mind is occupied with ornament in architecture that good architecture consists in so arranging the parts, their projections, heights and quantities to produce the effect of fitness, propriety and elegance, not in baving a handsome cornice, an exquisite bracket or any delicate carvings, but a certain modesty should pervade the whole and nothing should stand forth so ostentatiously as to rob the rest of their just powers of attraction.

It will be noticed that this plan has the square bay window. We cannot refrain from speaking a good word for this form wherever it is in harmony with the general design. We have found it much more satisfactory than the octagon shape, both from the greater interior space enclosed, the greater facility for viewing, and the harmony of the shape with a rectangular room within.

In the plat of the first floor given in the engravings, the following are the rooms and measurements: A, front porch; B, hall, 11 feet 11 inches by 17 feet 11 inches; C, parlor, 16 feet by 20 feet 7 inches; D, sitting-room, 13 feet 10 inches by 19 feet; E, dining-room, 17 feet 11 inches by 18 feet; F, kitchen, 16 feet by 17 feet 11 inches; G, store-room, 9 feet 1 inch by 9 feet 1 inch; H, side porch.

Mining Decision.

The Supreme Court of the United States bas, as a court of last resort, decided the case of the Flagstaff silver mining company, of Utah, vs. Helen Tarhet, affirming the judgment of the Supreme Court of the Territory of Utah. The following is the syllabus:

A location of a mining claim upon a lode or vein of ore, should be laid along the same lengthwise of the course of its apex at or near the surface, as well under the Mining act of 1866, as under that of 1872. If located otherwise, the location will only secure so much of the lode or vein as it actually covers.

Each locator is entitled to follow the dip of the lode or vein to an indefinite depth, though it carries him outside of the side lines of the location; but this right is based on the hypothesis that the side lines substantially correspond with the course of the lode or vein at the surface, and it is bounded at each end by the end lines of the location, crossing the lode or vein, and extended perpendicularly downwards, and indefinitely in their own direction.

If a location be laid crosswise of a lode or vein, so that its greatest length crosses the same instead of following the course thereof, it will secure only so much of the vein as it actually crosses at the surface, and the side lines of the location will become the end lines thereof, for the purpose of defining the rights of the owners.

A locator working subterraneously into the dip of the vein belonging to another locator, who is in possession of his location, is a trespasser, and liable to an action for taking ore therefrom.

The case was referred to before in these columns, when the Territorial Court rendered its decision, and attention is now called to it because the question is settled forever beyond all controversy.

CONCENTRATED sulphuric acid attracts water with such avidity that in a damp atmosphere it will double its volume in a few days. Chemists use it to dry air and other gases, and to keep instruments, such as balances, dry.

Coal Mining at Mt. Diablo.

[Extracts from Graduating Thesis of J. O'CALLAGHAN, University of California.]

The coal measures of Mt. Diablo are situated in a range of hills half way between the summit of the mountain and the San Joaquin river. This range is parallel to the San Joaquin, which is about five miles distant, and it is separated from Mt. Diablo by a deep valley. The altitude diminishes gradually from 1,700 feet in the western to 200 feet in the eastern part. The strata are tertiary, and are all elevated at an angle, probably by the mountain breaking through them. The general dip is to the north, being 32° in the western and 15° in the eastern part of the measures, which are about 12 miles long, as shown by the outcrop of the strike which runs in a general east and west direction. These strata are composed chiefly of heavy bedded sandstones, carbonaceous shales, clays and coal seams.

The mine of the Black Diamond Co. is situated in the most westerly portion, where the dip is greatest. This region is deeply dissected by narrow parallel canyons, which run from the San Joaquin plains to the summit of this range of hills. The canyon in which this company's mine is situated opens into a sort of

striking the Clark vein at a distance of 293 feet. At this level a gangway runs east and west on the seam, and on this, at a point 85 feet east of the foot of the Mt. Hope slope, is a counter-slope sunk on the seam, and at present worked to a depth of over 700 feet.

The slope and counter-slope are both double-tracked, and strongly timbered every three or four feet.

The cars are hoisted by a round three-quarter-inch rope. This passes over a pulley three feet in diameter and is then wound on a cylindrical drum six feet in diameter, the motion of which is regulated by a 12-foot fly wheel. The engine has a 14x30-inch cylinder, and hoists a car in about 30 seconds.

The counter-slope is fitted with a similar plan for hoisting. Though the slope was much better than a tunnel and had a greater production, still it is much inferior to a vertical shaft for many reasons. The incline necessitates a greater handling of cars and causes a greater loss of power. Two separate hoisting engines are needed, and one of these is underground, while only one engine is necessary for a shaft, and that one is on the surface near the boilers. The only objection to a shaft is the great outlay necessary for machinery, etc., before any coal is produced. But by using double cages and increasing the speed the production can be enormously increased.

The Black Diamond shaft is situated about 620 feet northwest of the Mt. Hope slope, being

DESIGN FOR AN ORNAMENTAL COTTAGE.

amphitheater, caused by the main canyon branching into three or four smaller ravines. Here are the hoisting works, coal bunkers dumps, etc., while a few hundred yards down the creek is the town of Nortonville, in which most of the miners live.

Although there are four seams of coal in the Black Diamond Co.'s property, only two of these are workable. These are about 1,000 feet apart, horizontally. The upper or Clark vein is of an average thickness of 28 to 33 inches, not being interstratified by slate or clay, but is all good workable coal, except where crushed by the bending of the strata. The lower or Black Diamond vein has an average thickness of from four to six feet, but it is not such good coal as the Clark vein, and it is more expensive

839 feet above water level. It has a rectangular shape, the dimensions being 22 feet 4 inches by 11 feet 10 inches from out to out. This is the most convenient form, there being no pressure sufficient to necessitate a round or square shaft. It is divided into three compartments. Two are for hoisting, and are six by nine feet inside. The third was designed for pumping, but is now used for ventilation, and contains a ladder which runs the whole depth. This shaft is very heavily timbered all the way down by one and a half foot Oregon pine, the sections being placed about two feet apart, and is a fine piece of work, requiring very little repairing.

At regular distances down the shaft levels are run out to strike the seams. The distance between two levels measured on the seam is called a "lift." The lift is made as high as possible, because every level entails an additional expense; still the height is limited by the difficulty of transportation and ventilation. The average height of the lifts in this mine is from 300 to 350 feet, this variation being caused by the change of dip in the seams. At each station there is a difference of level of six feet between the levels running to the two seams, so that by one stoppage, a car from each seam could be run on the double cage.

Machinery and Hoisting Plant.

In the case of the tunnel, a horse could be used to draw out the cars, and horse power could even be used as a motor to draw the cars up the slope; but steam now entirely replaces these more primitive means. There is a great saving by using steam, as the surplus power can be utilized in pumping and carrying on many of the minor operations, such as surface transportation, running the screens, etc.

When the Black Diamond tunnel was sunk, a very extensive system of hoisting machinery was adopted. At the mouth of the shaft is a well-braced and substantial hoisting frame constructed of heavy pine timbers two feet square. This frame is about 30 feet high, thus affording ample room for the cages to come above the surface without hitting the top. This frame consists of six principal uprights all slightly inclined and bound together by a firm rectangular frame or top in which the pulley wheels work. Two of these uprights, in the line of greatest pulling force, are much more inclined than the others so as to act as braces.

The pulley wheels, two in number, are the large wheels over which the cable passes. The diameter of these is five or six feet, and they are provided with guides to prevent the cable slipping off.

In the drums it is very important that the diameter be large, as a short bend is very destructive to iron rope. In Europe the average

drum is 20 to 25 feet, while here it is no more than five or six feet in diameter.

There are two kinds of drums in use at these mines; the ordinary wooden cylindrical drum for round cables, and the spool or bobbin drum for flat cables. The latter is used at the Black Diamond shaft.

There seem to be many advantages of the flat cable and bobbin over the round cable and cylindrical drum.

The flat cable winds upon itself and thus by increasing the diameter at each winding prevents the acceleration of a descending cage, which if the shaft were deep would necessitate a conical drum in case of a round rope.

The flat rope seems better than the round rope, as its diameter is less than that of round cable of equal strength. The flat rope can be mended easily and last for two or three years.

Two bobbins are fixed on the same shaft, and thus the engine has to hoist this weight of the coal, as the cage and empty car balance an equal weight of this other cage. By this means the motion is always uniform.

The engine used at the Black Diamond shaft has two horizontal 24-inch cylinders with five-foot stroke, and the power is applied directly to the shaft, thus doing away with a fly-wheel.

The foundation of the drum and engines is of solid brick built from bedrock.

The steam is supplied to the various engines by 10 large Cornish boilers, so connected that any two may be repaired without causing the others to stop. This great number is necessary because the only water available for use is mine water, and as this is very sulphurous, incrustations form very rapidly.

The steam pipes are packed in asbestos, but there is necessarily a great loss by condensation in pipes many hundred feet long.

The fuel used is the slack coal from the screenings, and many tons of this almost unsalable fuel are burned each day.

Opening Out.

Whether the seam be reached by an incline or by a level the same system of opening out and working the coal is adopted. The system here in use differs from the ordinary one on account of the steep dip and the thinness of the seams. From the point where the level reaches the seam a gangway is drifted to the right and left on the seam; the dimensions of this gangway are determined by the thickness of the seam, the strength of the roof and the requirements of transportation and ventilation. The average dimensions in these mines are 8 feet wide at the floor, 5 feet wide at the roof, and 5 feet from floor to roof.

By adopting this trapezoid form, the requisite width is obtained and the least support is removed from the roof. These gangways are given a grade of a few inches in a hundred feet. The floor consists of rolley-way and a rude channel on either side for drainage.

Faulting is a chief feature of this mine, and it causes great difficulty in drifting. Almost every case is that of a simple slip, in which the strata on the hanging wall have sunk. The direction of the gangway must then be changed until it again cuts the seam, and it must cut it in such a way that the foot wall of the seam is about four feet from the floor of the gangway, so that care can be easily loaded from the shoots.

Working the Seam.

Every 20 feet along the gangways on the seam shoots four feet wide are run up the seam, only the thickness of the seam being worked out. Safety pillars of coal 20 feet square are left all along the upper part of the gangway. The face of the seam is thus worked by a system of irregular steps.

As the coal is detached from the mass, it is allowed to slide down the shoots on slides constructed of sections of old boiler iron, which are laid so as to overlap one another. Thus by the simple action of gravity the coal may be transported several hundred feet, and by opening the mouth of the shoot it may be loaded into cars in the gangway.

Timbering.

Pine and redwood are the only materials used for timbering. All timbers are cut outside and are numbered so that they can be sent in and fitted without further trouble. The stations and levels being the most permanent, are strongly timbered with the heaviest timbers. The method of timbering the gangways is very simple, consisting of two uprights surmounted by a cap piece or crown. The uprights are inclined, so as to shorten the crown piece without losing space. The size of the timbers is eight feet long by eight by ten inches in cross-section. These timbers need continual repairing, some being replaced every two or three weeks. On an average the timbering is replaced every three months. The slopes are timbered with redwood pieces four by six inches.

Underground Transportation.

The cars are of such a size that when loaded they can be easily handled by one man. The usual capacity is one ton of loose coal. They are made of heavy pine planks strongly banded with wrought-iron. The internal dimensions are: Length, six and one-half feet; width, two feet two inches; height, in front, two feet five inches; in rear, two feet eleven inches. These cars run on ordinary strap rails, which are spiked on wooden stringers. The gauge is three feet. Trains of from five to six of these cars are drawn from the working parts of the mine to the shaft by single horses. The average distance is over one-third of a mile.

Hoisting.

The cage is made of iron and has two plat-

First Floor.

to work, the roof and the floor being composed of shale and clay.

Opening Up.

Formerly these mines were worked by running in horizontal tunnels to the seams, but this was not profitable only to a limited depth, and this means of opening up is now entirely abandoned. In the case of a tunnel there is no outlay necessary for hoisting or pumping, as the mine drains naturally.

The next method of reaching the seam was by an inclined shaft or slope run in at right angles to the seam, and after striking it, a counter slope was sunk on the seam.

The incline now in use, and through which most of the coal has been hoisted, is called the Mt. Hope slope. It is situated at the head of the principal ravine, 797 feet above low water, and is sunk at an angle of 37° 15' to the south,

forme six feet apart. Each platform is provided with tracks for the cars. The time of hoisting is one minute for 400 feet. At the top of the shaft is a light wooden railing, which is carried up by the cage, leaving the way clear for the cars to be run off. As a security against accidents, the cage is fitted with a safety-fastening for the cable and a safety-catch to prevent the cage falling to the bottom. A good deal has been written about safety-catches and many kinds have been suggested. Generally after an accident some such device has been adopted. After awhile the men, relying on the security of the invention, become careless, and thus invite another casualty. Also from long disuse the apparatus may be out of working order, or, if constantly in use, it may become worn out when most needed. The safety-catch adopted at this mine consists of two eccentric cog-wheels, so arranged that if the cable is loosened a powerful spring forces these eccentrics to grip the sides of the guides. This seems to be very effective, and does not disturb the timbering or destroy the guides. The safety-fastening of the cable is a device to prevent overwinding by unloosening the cable if the cage goes above a certain light.

Surface Transportation.

When a loaded car arrives at the surface, it is rolled off, an impetus being given it by rolling an empty car against it. The car is switched onto its appropriate track according as it goes to the dumps or to the bunkers. The bunkers are situated about 500 feet from the mouth of the shaft. Between these places there is a double track, built on a trestle, having a slight grade toward the bunkers. Over this track runs a slack endless wire cable one inch in diameter and jointed at intervals of eight or ten feet, by ewivel joints. On the back of each car is an iron plate with notches in it. As the car is pushed under this cable the joints catch in the notches and the car is drawn to the bunkers. This cable is kept in motion by a small, one-foot stroke engine, which turns a patent grip pulley about four feet in diameter. The average time of a car, from arriving at the surface to dumping, is about three minutes. Thus, in the entire operation, the coal is brought from the face of the seam to the bunkers without being transferred from one car to another.

The dumping is performed by an ingenious automatic-dumping platform. The forward end of the car is a door, which is suspended from the top by a rod acting as a hinge. This door is secured by a latch. The car runs on a small platform about four feet long, on which a track is laid, the ends of which are curved up to fit the wheel of the car. This platform is hung on side trunnions two feet above the rails, and by the impetus of the loaded car and the shifting of the center of gravity, the whole platform tips forward. There is a piece of curved iron so arranged that it will strike under the latch, and thus throw open the door, allowing the coal to dump on the screens below.

There are two of these dumping platforms, supplying two sets of screens, which are given a "jigging" motion by the small engine that runs the surface cable. The coal is picked and sorted by men and boys, who break the larger lumps by small picks and sledges, and cast the "bone" aside. The screens are at an angle of about 33°, and separate the coal into two grades. The marketable coal passes into bunkers, which hold about 1,600 tons. The coal is carried to the river by trains of coal cars made of sheet iron, and carrying about four and a half tons each. They are dumped at the wharf by a dumping platform similar to the above but worked by machinery. The cars descend by the action of gravity, and are drawn back by a small engine.

Ventilation.

Good ventilation is of more importance in coal mines than in any other on account of the danger, not only of impure air, but also of highly explosive gases. There are many causes of impure air, such as high temperature, breathing of men, burning of lamps and slow combustion of coal and sulphur, decomposition of wood and accumulation of gases from the coal. Blasting is now done away with, except in safe places. The Davy lamp is used to test all places in which the gas may have formed. Sulphurous acid and sulphydric gas are very abundant in some parts of this mine.

The mines are admirably located for good ventilation. Several different devices have been used to cause artificial ventilation, but the one which seems most successful is the one now in use. There is a large fan-wheel at the mouth of the shaft. This wheel is 24 feet in diameter, the fan being 5 feet wide. It is run at a moderate speed by a 3-foot stroke engine. This fan-wheel draws the air out of the mine by a separate compartment. About two-thirds of the air goes down the hoisting compartments, and the remainder through an old ventilating shaft. By means of a system of canvass and wooden doors in the main gangways the air is made to traverse the smaller workings where it is most needed. There seems to be ample ventilation even in the remote portions.

Drainage.

These mines are also well situated for drainage, as the water naturally accumulates in the lower levels. The water is forced from each level to the level above by a double system of force pumps. The volume pumped out daily is immense, and does not vary much with the seasons.

Lighting.

The miners use small portable oil lamps which

can be hooked on the cap. Each one supplies his own oil.

Losses of Coal.

The losses in this mine are very slight, and are more the result of mechanical crumbling of the coal which forms unsalable fuel; very little coal is left standing in the mine.

Production.

The Mt. Diablo mines have produced up to 1877, about 1,875,000 tons of coal.

The Black Diamond mine is under the management of Mr. M. Morgans, and it is due to his kindness that I have been able to obtain the above facts.

USEFUL INFORMATION.

GEOGRAPHICAL PROBLEMS SOLVED.—Within the present generation, and mainly during the present decade, nearly all the great geographical problems left us by our adventurous ancestors have been solved; all the great lines of exploration have been taken up and worked out with a success that leaves to the future only the details to fill in. The northwest passage was completed more than a quarter of a century ago; the Australian interior has been crossed and recrossed within the past few years; several bright lines now break up the once mysterious darkness of the "Dark Continent;" the sources of the Nile have been traced, and the course of the Congo all but laid down; the Russians have filled up many important blanks in Central Asia; there is now no mystery to speak of for geographers on the North American Continent, and none of any magnitude on the South; even the great outlines of the ocean-bed have been charted, and now at last, after a struggle begun more than 300 years since, the northeast passage has been made with an ease that makes one wonder why it was not done long ago. A matter-of-fact Swedish professor has shown that with a suitable ship at the proper season this long-sought-for passage to the "Far Cathay" is a question of only a few weeks. Of Arctic feats there now remains only the "dash at the Pole," and that the North Pole will be reached sooner or later there can be no doubt.

FIRE-PROOF MINING TIMBER.—A Glasgow engineer, D. R. Gardner, recommends the following as a remedy against accidental ignition of the timber in mines: When he desires to strengthen, harden, densify, season the timber and preserve it against decay and attacks of worms and insects, he merely dissolves and removes the sap, which he does by placing the timber in a tank and subjecting it to the action of neutral vapor, separately or combined, and in any order, and the process may be carried on continuously or intermittently from about 6 hours to 84 hours. He preferably begins with the neutral vapor, then alkaline vapor, the neutral vapor or fumes of mercury; the time may be 24 hours for each of the first three steps, and 12 hours for the last, which should be the fumes of mercury, if for preservation. The alkali and acid may be applied by being put into the boiler or otherwise, and the vapors can be tested by litmus paper, as to their neutral alkaline or acid state. The mercurial fumes are created by mixing equal quantities by weight of mercury and nitric acid, and allowing them to escape in the tank.

AN EFFECTIVE GATE-FASTENING.—We recently saw a neat, cheap and effective method of fastening a gate. It was in use on a ranch in Sutter county, and is, we have understood, unpatented, so that, if we can make its method evident, our readers may use it everywhere. The gate is hinged, and swings in the usual manner, except that it is best to use hinges which will allow it to swing either way with equal ease. Plant the gate posts so that the gate will swing past. Then take a piece of inch iron, either square or round. Let it be three times as long as one side of the square scantling used at the end of the gate. Bend it, in a forge, to a shape similar to the upper part of a letter T, or like three sides of a square. Cut a notch in the post at any desired height, and fasten this iron in by a staple, so that when lifted up the gate slips past either way, but when dropped it clasps the end of the gate. If properly cut, the notch will keep it from dropping past a horizontal point, and cattle will hardly find out how to open it.—*Exchange.*

STEAM-PROOF CEMENT.—*Dingler's Polytechnic Journal* gives a description of the manufacture of a new steam-proof cement, discovered by Mr. A. C. Fox, which, it is claimed, is not affected by hot or cold water, nor by acids or alkalis. First, a chromium preparation is made in the following manner: 2.5 parts, by weight, of chromic acid are dissolved in a mixture of 15 parts of water and 15 parts of ammonia. To this solution about 10 drops of sulphuric acid, and, finally, 30 parts of sulphate of ammonia and 4 parts of fine white paper, are added. When about to be used, gelatine dissolved in dilute acetic acid is added.

PROTECTING LEAD PIPE.—The *Revue Industrielle* says that the interior of a lead pipe can be covered with an incrustation of sulphide of lead by making a warm concentrated solution of sulphide of potash flow through it for 10 or 15 minutes. Pipes thus treated seem to be covered with grayish varnish, which prevents the water flowing through them from acting upon the lead.

EXPLOSIVE FORCE OF DYNAMITE.—We learn from the *Scientific American* that there is a misconception about dynamite exciting a greater force downward and gunpowder upward when exploded. Nitro-glycerine (the explosive agent in dynamite) yields on exploding about 900 times its volume of gas; gunpowder but 300. This gas, suddenly liberated, must displace a portion of the atmosphere, which presses with a weight of about nine tons upon each square yard of surface. To lift such a weight in the exceedingly short space of time occupied in the explosion of a charge of nitro-glycerine (in the form of dynamite or otherwise) would require a force greater than to split a rock, and the rock yields. Gunpowder yields but one-third as much gas on exploding, and the complete combustion of its grains requires an appreciable amount of time. Nitro-glycerine explodes all but instantaneously.

PRESERVING INSECTS.—A. Labouliere recommends plunging the insects, in the fresh state, into alcohol which has been saturated by digestion with arsenious acid (1½ pint will take up about 14 Troy grains of arsenic). The living insect put into this preparation absorbs about 0.003 of its own weight. When soaked in this liquid and dried the specimens are safe from the ravages of moths, *anthrenus* or *dermestes*. This treatment does not affect the color of blue, green or red beetles, if dried after soaking for 12 to 24 hours. *Hemiptera* and *orthoptera* can be treated in the same way; also the nests, cocoons and chrysalides of insects.

TRICHINOSIS.—In some of the Eastern States to find trichina in pork is no uncommon thing, but in Oregon such meat was unknown until a few days ago, as the following proves: Willio Palmer, living near Monmouth, died some time since, and Dr. Shipley has discovered that his death was caused by eating trichinous pork. A piece of muscle taken from the body of the dead boy was sent to this city, and under a microscope shows the parasites in great numbers. This is the first case of the disease on the Pacific coast, we believe.—*Portland Standard.*

TO CUT A HOLE IN GLASS.—To cut a round hole in a pane of glass of any required size so as to save the pane, use a copper tube of the size of the required hole; revolve it in contact with the glass, and supply it with emery and water.

GOOD HEALTH.

On Diphtheria.

Dr. E. M. Snow says, in his last report as Register of the city of Providence:

In connection with this subject I think it my duty to ask the attention of the people of Providence, and especially of parents, to the following statements:

1. No case of diphtheria occurs without an adequate cause. This is self-evident.
2. The cause of nearly all cases of the disease exists in the houses or premises, or within a few feet of the houses where the cases occur.
3. The cause of nearly all cases that occur in the city is breathing impure air from privy vaults or sink drains, or cesspools; or drinking impure water.

Much observation and long-continued and careful investigation have perfectly satisfied me of the truth of these propositions, and they are applicable to all cases, whether in the tenements of the poor or in the mansions of the rich.—*Med. and Surg. Reporter.*

Origin of Diphtheria.

Diphtheria is believed to have originated in Egypt more than 2,000 years ago. It prevailed in Egypt and Asia Minor, to which it extended, during the first 500 years, and hence was early called an Egyptian or Syriac disease. Having invaded Europe, the disease appeared in Rome, A. D. 330, and being highly contagious, in its 1,500 years transit on the continent of Europe, it affected mainly rural districts and garrisoned towns. It extended to Holland, in which it was epidemic in 1337; to Paris in 1576, and again appeared there in 1771. It prevailed more extensively in France in 1818 and 1835, and in England, the United States and Canada from 1856 to 1860, and more or less since.—*Hospital Gazette.*

Is Glucose Candy Wholesome?

If a manufacturer is really conscientious, he must give up the use of glucose in candies, or at least use it very sparingly. We know it will be a sacrifice, as glucose can now be had for from three to four cents a pound, while cane sugar costs about four times as much; but we are of the opinion that it is decidedly injurious, especially for those who have a tendency to dyspeptic sourness of the stomach, and this for the following reason: When cane sugar ferments, it changes first into grape sugar; it is the same with the starch in corn, wheat, barley, potatoes, etc., which, with the help of plenty of water and some heat, break up into dextrose and glucose—we say break up, as the fermentation is a destructive process, which in its gradual career of disorganization changes elaborate organic compounds into more simple ones. If the fermentation is stopped by drying the grape sugar it is the end of it for the time being, but if the grape sugar is again dissolved in water and properly diluted, fermentation will go on to a further stage, and the result will be alcohol or vinegar, according to the temperature; if this is

kept down to about 50° Fah. alcoholic fermentation will take place, and every molecule of grape sugar will be broken up into two molecules of alcohol and two molecules of carbonic acid; if the temperature is above 70° Fah., acetic fermentation will take place, and the grape sugar will be broken up into acetic acid, hence two kinds of fermentation are acknowledged by chemists—the alcoholic and the acetic. Brewers always want the first kind, as otherwise they would brew sour beer. This is why they use so much ice in summer; in olden times, before the use of ice was so common, they had to close their breweries during the summer, as they could not work—at least could not brew good beer. Now, in the human stomach the temperature is always above 70° Fah., and the conditions for acetic fermentation are favorable. If the digestion is vigorous the sugar is absorbed before fermentation takes place, and persons with strong digestive powers can often absorb grape sugar before it has time to ferment and become acid; but when the stomach is in the least weak or slow in its action, it has time for this, and sourness or dyspepsia is the result; such persons may be able to digest cane sugar, as this takes much longer to enter into acetic fermentation, as it must first turn into grape sugar or glucose. For these reasons it is not advisable to use grape sugar, and therefore we earnestly warn all persons troubled with weak digestion or sourness of the stomach to avoid the new fashioned candies, even if they are called "old-fashioned molasses candies." They are almost all made of glucose, and nothing else. If you want ewcots, take a lump of good white or crystallized cane sugar, then you know what you are eating; but when you eat candies you do not.—*Manufacturer and Builder.*

Drug Taking Mania.

Women are rather more given to drug taking than men, though both are had enough in this respect. Here is what one of our most eminent physicians has to say on this subject:

"Dr. Holmes has said that it would be well for the world if most medicines were thrown into the sea; that it might be bad for the fishes, but it would be better for mankind. For this unasked and impertinent suggestion he has received a good deal of orthodox censure, which I am here now to share with him, for I am of the same opinion as Dr. Holmes, and this opinion has long been a part of my Christian faith. That the major part of the world does not agree with us is plain. Indeed most people seem to think that the chief end of man is to take medicine. Babies take it in their mother's milk; children cry for it; men and women unceasingly ask for it. Shrewd men have taken advantage of this instinct, and in most civilized nations it is to-day one of the chief articles of manufacture and commerce. It is one of those things which is never permitted to be out of sight; but is thrust upon you in the nursery, in the streets, upon the lamp posts and upon the curbstones, along the highways, from the rocks which border the rivers; the medicine chest follows you at sea, as if the sea itself, a vast gallipot of nauseants, were not enough. One might naturally suppose that the supply would at length exceed the demand! but it does not. Everywhere the people are stretching out their arms and haggling for medicine, blessing him who gives and cursing him who withholds. They believe, in their simplicity, that if medicines do no good, they can at least do no harm. They imagine, also, that there is a medicine which may be regarded as a specific for every human malady, and that these are known to science, and that therefore we have the means of curing all diseases; but the people imagine a vain thing. Whatever medicine is capable when properly administered, of doing good, the same medicine is equally capable, when improperly administered, of doing harm; and drugs often substitute a malady more serious than that which they were intended to cure. The Irishman said his physician stuffed him so with medicine that he was sick a long time after he got well.—*Dr. Frank Hamilton.*

BRAIN WORK AND SKULL GROWTH.—The *London Medical Record* sums up as follows the results of some very interesting measurements of heads by two French physicians, Messrs. Lacaze and Cliquet: Having the patients, doctors, attendants, and officers of the Val de Grace at their disposal, they measured the heads of 190 doctors of medicine, 133 soldiers who had received an elementary instruction, 90 soldiers who could neither read nor write, and 91 soldiers who were prisoners. The instrument used was the same which hatters employ in measuring the heads of their customers; it is called the conformatore, and gives a very correct idea of the proportions and dimensions of the head in question. The results were in favor of the doctors; the frontal diameter was also much more considerable than that of the soldiers, etc. Nor are both halves of the head symmetrically developed; in students, the left frontal region is more developed than the right; in illiterate individuals, the right occipital region is larger than the left. The authors have derived the following conclusions from their experiments: 1. The heads of students who have worked much with their brains are much more developed than those of illiterate individuals, or such as have allowed their brains to remain inactive. 2. In students the frontal region is more developed than the occipital region, or, if there should be any difference in favor of the latter, it is very small; while in illiterate people the latter region is the largest.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Tucson, Arizona; Public Steam Heating; Intersecting Cable Wire, 17. The Week; They Inaugurate the Game in New York; Gold and Silver Production of the World; Mining as King; To Correspondents, 24. The Bennett Polar Expedition; Alaska as a Mining Field; Harvest Field Disaster, 25. ILLUSTRATIONS.—City of Tucson, Arizona, 17. Design for an Ornamental Cottage, 22. Capt. Howgate's Map of the Arctic Regions, 25.

CORRESPONDENCE.—Carson and Vicinity; Mono County Mining Interests—No. I; Breaking up Slag with Rock Salt, 18. The Great Western Quicksilver Company, 23.

MECHANICAL PROGRESS.—Steering Made Easy; Submarine Engineering; Printing Press Marvel; Narrow-Gauge Railways; Tin Plate Manufacture; Spiders Killing Trout; A New Road Locomotive; Improvement in Chandeliers, 19.

SCIENTIFIC PROGRESS.—The World in Wax; New Antiseptic Salt; Indian Steel; Chinese Porcelain; Tough Old Iron; New Dye; Coating Iron with Iridescent Copper; The Spectroscope and High Temperature; Position of the Planets for July; Selenium Camera; Color of the Electric Light; Polarized Light in Gases; Transmission of Power by Electricity, 19.

MINING STOCK MARKET.—Sales of the San Francisco, California, and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 20.

USEFUL INFORMATION.—Geographical Problems Solved; Fire-Proof Mining Timber; An Effective Gate-Fastening; Steam-Proof Cement; Protecting Lead Pipe; Explosive Force of Dynamite; Preserving Insects; Trichinosis, 23.

GOOD HEALTH.—On Diphtheria; Is Glucose Candy Wholesome? Drug Taking Mania; Brain Work and Skull Growth, 23.

MINING SUMMARY from the various counties of California, Nevada, Colorado, Idaho, Montana, Oregon and Utah, 21-23.

MISCELLANEOUS.—Brains; On the Metallurgy of Platinum and Iridium; Hypnotism and Science; The Blessing of Labor; Low Water in Boiler, 13. Ornamental Cottage; Mining Decision; Coal Mining at Mt. Diablo, 22-23.

NEWS IN BRIEF on page 28 and other pages.

Business Announcements.

Diamond Drill For Sale, Pacific Land and Trust Co.
 Golden Gate Academy, Oakland, Cal.

The Week.

Among the more notable events of the week in connection with mining matters, we have the non-payment of June dividends by the Con. Virginia and the California companies, the only Comstock mines that have of late been making any net earnings, and we might also say any earnings at all. To a pitiful sum indeed has the product of the great Washoe lode been reduced, and unless it shall undergo early enlargement we cannot see what is to keep up the prices of Comstock shares much longer. By some seeming fatuity the bullion output of these mines is in the inverse ratio of the facilities furnished for making it. With the multiplication of mills, the extension of exploration and provision for deep drainages, their gross earnings have undergone steady shrinkage, raising the question whether some of this expenditure may not have been premature—whether these costly works for drainage and reduction should not have followed instead of preceding ore developments. Let us, however, hope for the best.

From the Bodie mines cheering accounts continue to reach us, the late ore finds in the Standard and Bodie improving with both downward and lateral exploration. The news comes to hand this week of promising quartz mines being opened in Alaska, some account of which will be found in another column. The constant appreciation of silver gives encouragement to those engaged in mining for that metal, and will very likely lead to the re-opening of some mines now closed, and generally stimulate this branch of vein mining. Subsidiary silver coin is now worth in this city very nearly as much as gold; the discount on half dollars not exceeding one-half of one per cent., a good deal being taken by brokers at one-tenth of one per cent., and some at par. Water holds out well with the hydraulic miners, many of whom still continue washing operations and, with a diminished water supply, will be able to do so for several months to come. The water season has, in fact, been prolonged beyond expectation, and this class of miners will make a full average clean-up of gold this year.

They Inaugurate the Game in New York.

Through all channels of intelligences we are advised of a growing interest in mining affairs at the East. This information, announced first by telegraph, receives later confirmation through private letters and newspapers coming to hand from that quarter. The New York Times, of recent date, remarks that the evidences of a growing disposition to speculate in mining shares are too numerous and palpable to be mistaken. In anticipation of increased activity in this class of securities, the price of seats in the mining stock board of that city has recently advanced several hundred per cent. Brokers, who before carefully eschewed this class of paper, are now operating in it extensively. Numerous mining companies, with flaming circulars and officered by prominent politicians, are being formed there, who, immediately they are organized, proceed to widely advertise their properties, purposes and prospects. Every little exchange shop down town has its freshly written placard announcing all kinds of mining stocks bought and sold within. Claim owners, agents, experts, middlemen and promoters of every description fill the hotels and swarm about the business centers, the inevitable "process man" being also present with his clever methods for extracting the precious metals, from the most obdurate ores, closely, quickly and cheaply. Many of the knowing ones, men early to perceive the tendencies of the times and accustomed to forestall the coming market, have gone, or are about to go, West for the purpose of buying, bonding or otherwise securing control of mining properties; but desirous of seeing for themselves and saving the commissions of go-betweens.

Observing these things, the Times justly concludes that they indicate a growing excitement about mining matters, which, if suffered to go on unchecked, will be very likely to lead to widespread and ruinous speculation. We think there is a danger of this. Even at this distance it looks to us that way. These are the symptoms that usually precede an unhealthy activity in the mining share market. This gathering of mining sharps and adventurers in Eastern cities; this multiplication of "bucket shops" there; these numerous, respectfully headed and well advertised mining companies, with such great appreciation in the price of seats in the stock board, are the sure forerunners of a big gamble in this class of securities. This is the sort of machinery manipulators employ for enticing the masses and popularizing the shares of these mining companies. When we see recourse had to these methods of procedure, with their exhibition and blare, we know what it means: It means gain to the few and loss to the many. It means seeming and short-lived prosperity to be followed by general distress and injury to every branch of legitimate business, including mining itself, which latter is harmed more perhaps than any other industry by these seasons of undue inflation and reckless investment.

To those who have fully made up their minds to engage in this species of gambling, we have no advice to give, for the reason that they are apt to be either too well informed to require or too illy informed to feel the need of any kind of advice. Nevertheless, there may be those prepared to profit by the experience which we on this coast have had in this and other speculative branches of mining. With us the errors and abuses attendant on gold and silver mining have, in the several epochs of this business, taken on various forms and phases. Overlooking the mistakes of the pioneer miners, which were mostly of a practical kind and confined in their effects to those who committed them, we will here briefly advert to some of the evils that subsequently came to be engrafted upon this industry and the mischievous ends it has been made to subserve.

Under the stimulus imparted to vein mining, through the discovery of the Comstock lode, thousands of prospectors turned out to search for this class of mineral deposits, the most of whom, making their way over the Sierra Nevada, proceeded to explore the regions beyond, where they lost no time in locating innumerable claims, the most of which were, of course, wholly worthless. These claims were made the basis for the organization of a great many companies, incorporated with a large number of shares and an immensity of nominal capital. Then followed a season of general excitement and speculation. Everybody was loaded up with these mining shares, the rich and the poor alike engaging in the traffic. By-and-by it turned out, as should have been foreseen from the first, that these mining claims possessed little or no merit, and the whole community became losers. And so the people on this side received their first lesson in speculative mining.

Meantime a mining stock exchange had been started in San Francisco and got down to business. Having prospered, this institution was followed by three others here and a fourth planted in Virginia City. Through a long series of years the most of these establishments were well sustained, some of them having flourished exceedingly. Of late, however, their patronage has begun to fall off. Sales have diminished and business languishes to an extent that threatens its early extinction. It is impossible longer to enthrone the masses. To get up an old-fashioned sweeping deal seems out of the question. Manipulators find it necessary to use

fresh bait or angle in other waters. In this extremity those in interest are seeking to transfer the business to a more appreciative constituency and a more genial soil. Californians having been milked to the strippings, it is meet that the milking machine be taken hence to perform a like service where the luscious fluid remains still abundant. As it may suit these Orientals to stake their money on this sort of a layout, we shall not object to the removal. They are welcome to the gambling arm of the business so long as the mines and their legitimate proceeds are left to us. The game, though not wholly new, may serve to slightly diversify their old methods and make them more attractive. We wish them a happy experience with their new acquisition, hoping they will find delectation in it while it lasts, and have happy riddance of the institution when they have had enough of it. They have already establishments in the great Eastern metropolis akin to these stock exchanges. To discriminate widely between the operating methods employed in the mining bourse and those in use at the place of the man Morrissey involves distinctions too nice for our unschooled casuistry.

On the character of the men who are seeking the advancement of mining schemes in the East we forbear to comment. If the people there fail to make early discovery of their true worth, they possess less discernment than we give them credit for. But this we will say, some of these are men to be trusted and some are not; whereas those who deal with them will be liable to get good bargains and bad. To parties abroad who propose engaging in the business of mining on this coast in a practical, business-like way, we take it upon us to say there never was a better time for doing so than the present. With the experience now gained, mining for gold and silver here, offers better inducements for the investment of money than any other industry whatever. If those about to embark in it will only observe the same caution, economy and general good management, that is deemed essential in every other pursuit, they cannot fail of success in the end. Prosecuted under these conditions it is not only the safest but also the most profitable and every way satisfactory business that to-day invites capital and enterprise either here or elsewhere. The California gold mines are now yielding better profits on the money and labor expended upon them than ever before. Those working them, whether in a large or small way, are nearly all doing well. Scarcely anyone is losing money at the business now. It has been advanced beyond that stage, and promises hereafter to do better and better with each succeeding year. Let those who purpose becoming interested in mining avoid stock gambling, and, embarking in the business in a prudent way, follow it up as the great body of miners in California have done, and, our word for it, they will have abundant reason to be content in the end.

Gold and Silver Production of the World.

At a time when silver is to become a powerful factor in influencing European trade, Dr. Soetheer affords an opportunity to ascertain what the production of the precious metals has been during the last few centuries. Between the years 1493 and 1875, a period of 383 years, the known production in weight of the precious metals was: Gold, 25,234,954½ pounds troy; silver, 483,770,779½ pounds troy. Some uncertainty must always attend an estimate of this description, extending as it does over so great a space of time, yet in the main the above amount is substantially correct. During a century and a half the proportion of value between silver and gold dropped from about a ratio of 10.7% to about one of 15.5%, and remained at that point for about two centuries more. The proportion of gold produced, to silver, was far larger from 1851 to 1875, than during the earlier periods. From 1876 to 1878 there has been no important change in this ratio, and we may expect that the value of gold is naturally more likely to drop than that of silver. The sudden action of Germany in throwing an immense mass of silver on the market, derived from the surplus silver coin of that country, when a gold standard was adopted, and of France and the Latin Union in declining to receive it overbalanced the natural laws governing the question. But the effect was only temporary, as appears from the reaction already set in by Italy demanding a release from her obligations not to coin silver, and the equilibrium is nearly recovered already. The proportional relation of value between gold and silver is mainly independent of legislative action, and all that legislation has ever done or possibly can do, aside from exercising a depression, is to record the results developed by industrial activity. J. S. Mill says "money, like commodities in general, has a value dependent on, and proportioned to, its cost of production; the theory of money is, by the admission of this principle, stripped of a great part of the mystery which apparently surrounded it." The relations of value between gold and silver adopted by most modern nations are relations justified by the proportion of the supply of the precious metals. Variations in the proportional value will continue, but the solution of these points must be left to the gradual development of the natural course of events.

Mining as King.

The immense mining industry developed on this coast, instead of showing any signs of weakening, continues to acquire additional magnitude every year, month, nay, day, has turned a flow of Eastern capital in this direction such as was never known before. The East, disgusted with the ordinary stock investments and bottomless corporations, have been eagerly seeking a solid foundation upon which to build a capitalizing structure, and it has found it in our mines. The gold, the silver, the solid enduring basis of wealth, exists there, really; and, besides its reality of existence, the chimerical windbags of Eastern wildcat-swindling companies collapse. Solidity was sought in the exciting fluctuations of the gold board of New York, and the brilliant bubble, so beautiful and satisfying when distance lent enchantment to the view, faded away at a touch and the visions of wealth became swallowed up in the despair of lost fortunes. Again was solid wealth sought in the plebeian schemes of Ohio and Pennsylvania, when to possess an oil well was the acme of human enjoyment and commercial importance. But oil flowed, burned, exploded and left not even a grease spot in the pockets stuffed with scrip and stocks into the millions.

Coal sought its devotees and the black shing requirements of household comforts and steam conveniences winked its shining eye alluringly at the wavering capitalist seeking for an honest penny. But its allurements were likewise fatal. Although possessing solidity it could glut the market; the supply could exceed the demand and pockets became depleted by a tremendous drain to satisfy the insatiable maw of expense.

Real estate, that ownership of the earth which all men seek, if only to lay therein their weary bones after life's fitful fever is over, became overloaded, and in falling smashed many a paper balloon of hopes and mortgages, demonstrating that men were getting nearer the real satisfying want, but had not yet reached it. Nothing that had been tried filled the vacuum, because the material possessed no intrinsic value, and could be used only as the basis of a valueless paper fabric of promises to pay.

At last, the bonanza developments showed a circulating medium of yellow shining eagles, having not only a commercial value, but a real intrinsic value, something for the flinty hearts of capitalists to love for its own sake, and as naturally as a duck takes to water, or as a business man takes to the bank for supplies—so went capital to the source whence these shining eagles were obtained. And so capitalists have found the right foundation, a foundation not built in sand but upon rich ore, containing gold and silver, articles capable of being directly converted into money by the stroke of a steel die. Something to spend, to stow away—a solid, enduring material, the musical jingle of which charms the ear of all humanity, and unfortunately more attractive than the music of angel voices. Our mines are flourishing, our rich mineral deposits so far from decreasing are increasing, and while it is true that every million taken from the mines decreases the value of the same by that amount, yet we are adding to the world's requirements a material, a commercial medium, which instead of lying dormant deep in the bowels of the earth, will circulate as infallibly as the ocean currents and for as long a time. Truly mining is now king! Recognized as such by the dominant voice of capital, and the East will continue to come to us as it must, or remaining aloof, fall into desuetude through lack of a friend near the throne.

To CORRESPONDENTS.—In the multitude of contrivances and processes now existing, it sometimes happens that an old invention will be described as new or attributed to some individual not entitled to it, and to this fact of multitude must be attributed mistakes. We desire nothing but new and useful facts without unnecessary individual laudation. The development of our mining and industrial conditions is always a matter of benefit. We hope our correspondents, captivated by local circumstances, will not invent what is old.

EXPLOSION AT BODIE.—As we go to press we receive news of the explosion of the Giant powder magazine near the Standard mine. Five tons of Giant powder exploded, completely destroying the works and the property in the vicinity. About 20 persons were killed and 50 wounded. The shock was felt 20 miles from the scene of the disaster.

It is estimated by English journals that the loss in wages occasioned by the late strike of colliers at Durham amounts to \$3,000,000, \$1,000,000 of which was borne by the men. Each miner has, it is said, lost \$25.60 in wages in a strike in gaining 1¼% better terms than the owners offered at first, 1¼% being 0.8 cent. in the dollar. The colliers will have to work 9½ years to recover the \$25.60 without reckoning interest.

A MINERS' Union has been started at Nevada City, under favorable auspices. It will have a membership of 200 in a short time.

The Bennett Polar Expedition.

The *Jeannette* has departed on her eventful voyage to the mysteries enclosed within the Polar circle, and with her and her brave crew have gone the best wishes of the nation for the successful attainment of the objects proposed. To us as a nation relying more upon individual effort than upon national interference will undoubtedly be awarded the solution of a problem so long sought but never solved. To follow the route of the noble sailors who passed Cape Farewell on the east coast never to return to their homes might have been regarded as unwise if not folly, but the same genius that directed the movements of Stanley in Africa, planned also the present movement upon a scientific theory, carrying with it every possible and probable element of success. Amply provisioned with everything that ingenuity could devise or imagination invent, and manned by tried men and true, the hearty farewell shake of the hand dispelled all doubts of courage and faith in the seaworthiness of the good ship and the successful issue of the voyage.

The numerous currents existing in this ocean have been the cause of the disasters attending former expeditions in search of the northwest passage by way of Baffin's bay. These ocean currents, the great rivers of the sea, move steadily on through waters comparatively tranquil, spreading over hundreds of miles upon the broad bosom of the ocean, not only upon the surface, but also in deep waters, often moving in different directions. The cause of these ocean movements is found in the difference of temperature between the polar and tropical regions acting directly upon the waters, the configuration of the continents exercising a certain controlling force as to direction and variation. The cold and heavier waters of the polar regions tend incessantly to flow into the warm and lighter waters of the tropics, and when both meet the colder waters sink and disappear below the warm waters, which return as surface currents towards the polar regions diverted from a perfectly straight course by the steady action of the earth's rotation and by continental obstructions. To illustrate this, place at one end of a glass vessel of suitable dimensions, filled with water, a piece of ice, and apply heat at the other end by means of a spirit lamp; then color the cold water end with carmine and the warm water end with indigo. A current of carmine will immediately flow towards the heated end and meeting warm water will sink, while the blue warm water will flow on towards the cold end, forming continuous currents of carmine and blue, one flowing towards the ice on the surface of the water, the other flowing towards the heat below the surface.

The Gulf stream, which is the current of the North Atlantic, affecting Arctic expeditions in that direction, arises from the accumulation of the waters of the equatorial current in the Gulf of Mexico. It proceeds east until its course is changed to the north by striking against the Bahama Banks. Flowing with great rapidity along the coast of the United States, gradually expanding in volume and diminishing in velocity as it proceeds northward, it turns east at the latitude of New York and crosses the Atlantic to the Azores, when it divides, the main branch returning southward along the coast of Africa, while the northern branch continues its slanting course to the British Isles and Norway. A branch of the gulf stream flows from about the latitude of Newfoundland north towards Iceland, and sweeping around in a semi-circle between Spitzbergen and Lapland, is divided into two branches by impinging against Nova Zembla, thence uniting its streams again in the Kara sea where it is lost in the Polar current. The Polar current, appearing at the eastern boundary of the Kara sea, flows steadily and rapidly around it and within the 80° parallel of north latitude, oftentimes within 7° of the north pole, forming the Polar channel, thence south between President land and Grant land, under the great ice barrier to Hall land, on the extreme northern end of Greenland, whence it is divided into two branches, the one flowing south along the east coast of Greenland, the other south along the west coast of Greenland through Baffin's bay and Davis strait, until reuniting after passing the most southerly point of Greenland it flows on steadily in one great current until it is lost by sinking beneath the gulf stream at or near the latitude of Newfoundland. This outflowing Polar current has been the cause of the failure of former Arctic expeditions on the eastern coast. The ship is either forced back away from the pole by the force of the current, or else locked in the ice, it is floated with it in its southern course out into the Atlantic, the main outlet of the north Polar waters.

Upon the Pacific ocean the great equatorial current, divided by the coasts of Asia and Australia, divides, and sends one branch south, the other flowing north bends to the north and northeast after passing the Philippine islands and Formosa and becomes the Japanese current (Kuro-Siva), the Asiatic gulf stream. This noble stream, with its vast body of deep blue and warm waters, flows swiftly along the eastern coasts of Japan slanting across the north Pacific to the peninsula of Alaska, one branch sweeping northeast directly through Behring's strait into the Polar sea. Thence sweeping

around along the north coast of America to the Arctic islands it unites with the eastern and southern flowing Polar current through the great ice barrier—Barrow's strait, Jones' and Smith's sound—uniting with and forming part of the great Polar current which finds its way to the Atlantic, carrying upon its bosom the ice of the Polar regions. In this current the *Jeannette* will be continually carried onward, east to the Atlantic ocean, as inevitably as she would be carried to this Gulf of Mexico by the current of the Mississippi. Whether frozen in the ice or not, she will be carried east to the Atlantic, or in the direction of the North Pole, by the steady flowing current in that direction. In fact, there is no current flowing in any other direction. The Polar currents all crowd to the east on the American coast, under the influence of the earth's rotation, and because the Atlantic is the only outlet, the shallow, narrow passage of Behring's strait preventing them from sinking under this warm Japanese current, so that from the Pacific to the Arctic ocean there is a constant inflowing current, and from the Arctic to the Atlantic a constant outflowing current, reason enough why the *Jeannette* should succeed if success will ever attend a Polar expedition. The scientific features of the expedition will be of the highest order. No observation will be neglected, whether made by deep sea soundings or in the air, for the benefit of meteorology. Every preparation has been made to provide for the comfort and safety of the men. Electric lights will be used for signaling, and these with 300 miles of wire with telephones, will enable the observers to communicate with the ship at a distance of 450 miles from her, so that sledging parties can report their discoveries or needs to those remaining on the ship. Amply pro-

Alaska as a Mining Field.

In some remarks published by us not long since and directed to a consideration of the proper course to be pursued by the general government in its management of our Alaskan possessions, we urged the policy of encouraging a thorough exploration of that region for deposits of the precious metals, pointing out how speedily it would be overrun by the hardy miners, in the event of either gold or silver being found there in remunerative quantities, and the government thus be relieved from the necessity of protecting the white settlers by the presence of soldiers as well as other care about the future of that country. Since the publication of that article we are in receipt of a letter from a reliable party now operating a quartz mill and mine on the island of Baranoff, and in which a very favorable account is given of the gold-bearing veins in that neighborhood, these, according to this authority, being not only numerous but of good size and promise. These mines are close to Sitka, so near, in fact, that the town is included within the boundaries of the mineral district organized since their discovery.

The finding of the precious metals in this section of the country is not a recent occurrence. They have been known to exist there for many years. The Indians, at the time the country was taken possession of by the Russians, were in the habit of wearing gold and silver ornaments of their own make, the metal having been first pounded from the ore with rocks and afterwards rudely shaped by smelting. Nuggets of gold, some of them of considerable size, have been

bold and well-defined outcrop for a long distance, and from 3 to 10 feet in width. With one exception, no ore has yet been milled from these lodes, but assays made and the prospecting done, denote for them a milling value of about \$30 per ton. The natural facilities here for both milling and mining are good, there being an abundance of water, and a superabundance of wood in the district. The whole country is, in fact, so heavily timbered, that it is difficult to get about, or construct wagon roads over it, while they have rain on an average, 20 days in every month. The streams being numerous and never failing, afford ample water power for the propulsion of machinery close to the mines.

From the foregoing it would look as if they might have a considerable extent of vein mines in the locality described, enough, if not to lay a sure foundation for a great mining industry in these north lands, at least enough to serve as a starter. With a mill already in successful operation, backed by resources so considerable, we have a good beginning in this branch of mining. As there is evidently room for more mills in this district, more will no doubt soon be put up there. Indeed, with the footing it has gained, we may consider quartz mining an assured industry in far-off Alaska. It will now be able to go on and take care of itself. But this is not a rapidly expanding and aggressive industry. It is cumbersome and slow of movement, and capable of invading this wilderness but slowly. What is now required to hasten the conquest of these savage lands and people, and take from the hands of the Government the heavy charge that now rests upon them of looking after the same, is the discovery, away in these wilds, of paying placers—the swift, rough civilizers, the forerunners of enlightenment, the advanced frontiers.

But it is an awful country, this that stretches away—indeed, we don't know where! Awful in its extent—almost as big as the whole United States besides—awful in the gloom and solitude of its forests, in its mountains, enveloped in mist and flaming with volcanic fires, and in its majestic rivers flowing into the unknown: A country, the exploration of which even the California prospector should not be expected to undertake without some special aid and encouragement. We therefore here repeat the suggestion made when before alluding to this matter, that the general government extend some assistance to such of our adventurous population as may feel disposed to undertake a trip to Alaska in search of mines and more especially placer deposits. If there are any such in that country this is the way to find them, and once found such a rapid influx of brave and hardy immigrants is sure to follow as will at once relieve the authorities at Washington from any more trouble about it, and convert a now useless and troublesome dependence into a populous and self-sustaining appendage of the government. If Alaska has anywhere in all her icy wastes even a moderate extent of surface diggings, our veteran prospectors will with a little help find their way to them and make them the means of infusing life into that dead and distant Territory. With a colony of miners up there it would not again become necessary for the English to dispatch an armed vessel to Sitka for the protection of American citizens, nor would the latter have cause to longer fear their savage neighbors. Let the government furnish a vessel giving free passage to as many miners as might choose to emigrate to Alaska, carrying also their provisions free and providing means for their return, and we doubt not a sufficient number of the right kind of men would be found ready to embark for that country, and that the results of such policy would prove highly satisfactory to all concerned.

Harvest Field Disaster.

About 3 o'clock Tuesday afternoon the boiler of L. B. Anway's steam thrasher, at work near Rio Vista, Solano county, exploded, injuring the fireman, Andrew Larson, so severely that he died within half an hour afterward. As the fireman was in the act of putting straw into the furnace the inside flue collapsed, blowing out the fire-box, the door of which struck him with great force. His clothing was saturated with hot water and steam and his face was somewhat scalded. Mr. Anway, who was standing beside the engine, within two feet of the fireman, says that the steam gauge indicated a pressure of only 85 pounds.

On Wednesday the Coroner's inquest was held, and after hearing the testimony of impartial experts who had examined the boiler subsequent to the explosion, rendered a verdict wherein they found that the explosion was the result of a defective boiler. The engineer testified that there was plenty of water in the boiler at the time of the explosion, and so far as can be ascertained, no blame is attached to him. Indeed, there was nothing in the evidence sufficient to inculpate anyone. The boiler, it appears, has served in its present capacity since 1873, prior to which time it had been in use on a dredger for a number of years.

FIVE HUNDRED tons of vitriol were recently set free by fire near Boston and emptied into a tributary of the Mystic Water Works. Thousands of dead fish attest the presence of the chemical and the people of Boston are naturally afraid to use the water.

CAPT. HOWGATE'S MAP OF THE ARCTIC REGIONS.

visioned for three years' voyage as to provisions, and safe for two years as to fuel, the officers and crew feel buoyant and cheerful, expecting nothing but success, in fact, determined to succeed. With six chronometers, chemicals, microscopes, and barometers of a new and perfect make, and a varied and valuable library, the 33 brave men who compose her full complement, will receive a schooling during her long Arctic sojourn, such as it does not fall to the fate of every man to receive. A strong, tight, comfortable ship, hatched throughout with felt and canvas, and all iron below decks carefully covered, the fate of the crew cannot be considered hard.

The route after passing Behring's strait will be governed entirely by circumstances—none has been or can be determined upon. The influence of the inflowing current will be permitted to determine the direction, for it is expected that this current will solve the problem of the Polar regions. After leaving San Francisco the ship will proceed to Alaska and receive additional supplies from her convoy, and then weigh anchor immediately for Behring's strait. Success to the *Jeannette* and to her mission.

The general course of the Polar current may be traced from the description by reference to the map of the Arctic regions on this page—for the use of which we are indebted to Dr. A. B. Stout, of this city.

FOUR HUNDRED THOUSAND persons are employed on the railroads in this country; 2,000,000 depend upon them for immediate support, and \$400,000,000 are annually paid to employees and persons furnishing supplies.

In searching the premises of the late Mr. Burke, at Clatsop, Oregon, a few days ago, United States bonds to the amount of \$3,000, with the coupons for 1880, were found sewed in the garment worn by the daughter.

picked up or pounded from the quartz croppings at various points since the American occupation of the country, and the Hudson Bay Company, as much as ten years ago, shipped from the adjacent Prince of Wales island a quantity of gold-bearing quartz, that on being reduced was found to pay well.

The mines here alluded to are, however, of recent discovery, these lodes having been first noticed by the United States officers stationed at Sitka some five or six years ago. These parties made a number of locations, on which some work was afterwards done. But being little acquainted with this style of mining and unable to cut the gold out of the rock with hatchets, according to their notions of the business, they desisted from its further prosecution, and, upon their being removed elsewhere, the mines suffered temporary abandonment.

Some two years later parties from Portland, Oregon, visiting the country took up what is known as the Stewart mine, formerly owned by and named after Major Stewart, of the army. This party proceeded to open their lode and put up a 10-stamp mill, but the work having been committed to inexperienced hands was so badly performed that the company was forced to employ a more competent superintendent, the party now in charge, who has been compelled to partially reconstruct the mill, which, only within the past month, has been got in condition for active operations. A clean-up has since been had and the quartz found to pay at the rate of a little over \$30 per ton, the hullion running about seven-eighths gold and one-eighth silver. The ore may be considered free milling, though carrying a large percentage of sulphurets that require separate treatment.

According to the statements of our correspondent, there are, in the district where he is operating, a great number of auriferous quartz lodes, nearly all of them well formed and of large size, being easily traceable by a

NOTICE TO THE MINING PUBLIC.

MESSRS. RANKIN, BRAYTON & CO., of the Pacific Iron Works, are the only parties authorized to manufacture HOWELL'S IMPROVED WHITE FURNACE under the license of this Company.

THE STETEFELDT FURNACE CO.,

By C. A. STETEFELDT, President.

Referring to the above, the undersigned would call attention to the fact that by a compromise recently effected with the STETEFELDT FURNACE COMPANY, they have secured the use of all the patents of said Company applying to

Revolving Cylinder Furnaces,

And are thus enabled to give purchasers the license of all patent claimants, to-wit:

WHITE, HOWELL, THOMPSON,

— AND THE —

Stetefeldt Furnace Company,

Thereby avoiding all further litigation in reference to these rival claims. The great

SUPERIORITY OF THE FURNACES

Embracing these patents has been satisfactorily demonstrated. There are now some thirty of them in operation in the various mining districts of the coast, operating in all cases with economy and satisfaction, working in many localities

THE BASEST AND MOST REFRACTORY ORES UP TO 90 AND 95 PER CENT.

By an improvement—the patent for which has recently been allowed—this Furnace can be readily adjusted so as to work with equal facility and effectiveness all classes of ores.

The following are some of the Mining Companies who have recently adopted this Furnace, the most of which are now in successful operation, many of them running two and some three and four Furnaces.

NEVADA.—Grand Prize, Star, Martin White, High-bridge, Columbia, Alexander, Paradise Valley, Jefferson, Leopard, Eagle, Endowment, Independence.

ARIZONA.—Tiptop, Tiger, Peck, Hackberry, Corbin, Tombstone, Bradshaw.

OREGON.—Monumental.

MONTANA.—Alice Mine, Butte City.

MEXICO.—Trinidad, Hermiguera, Pioneros.

PERU.—Cerro de Dasco.

RANKIN, BRAYTON & CO.,

Pacific Iron Works.

CAUTION.—All persons are hereby cautioned against buying from other parties Furnaces embracing the improvements covered by the patents above mentioned, as they will be vigorously prosecuted and involved in heavy damages.

WASHING! WASHING!

Prices Reduced! Prices Reduced!

La Grande Laundry,

13th Street, Between Folsom and Howard.

PRINCIPAL OFFICE,

648 Market Street, S. F.

Office open from 7 A. M. to 9 P. M. Saturdays to 11 P. M. Washing called for and delivered to any part of the city free of charge.

All orders receive prompt attention. For circular and rice List apply at the Office,

648 Market St., San Francisco.

PALACE RESTAURANT

218 Sansome St.

This elegant and spacious S. F. Restaurant has been re-opened with superior bill of fare daily, and is now the best and most popular dining saloon on this Coast.

Resident business men and visitors from abroad will be wise in giving this place an early call. Examine bill of fare and prices.

HERMAN H. HORST, Prop'r.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery, Spanish Sparilla. Unexceptional references. Address EXPERT, this office.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, PROPRIETOR.

THE ELKINS

"BOSS" GOLD AMALGAMATOR,

Is the Best, Simplest and Cheapest Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 100 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 3-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 381 Pine Street, - - - SAN FRANCISCO.

Pioneer Plating Works.

MANUFACTORY OF

Silver Plated Amalgamating Plates,

For Quartz Mills and Cravel Claims. Are prepared to furnish any size Plate promptly and satisfaction guaranteed. Old Copper Plates purchased, Plated or the Gold Extracted by the most complete process, at small cost, and the copper saved.

JOHN MORRISON, Proprietor.

No. 717 Mission Street, near Third, - - - - - SAN FRANCISCO, CAL.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to their advantage to consult with us and in case of necessity secure the services of our home and Washington branch agency.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, O. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the heights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1378. Sold by DEWEY & CO. Price, postpaid, \$2; to subscribers of this journal, until further notice, \$1.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or bulking material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of OROSS & CO., San Francisco.

C. C. Bitner's Apparatus for Obtaining Metallic Copper from its Solutions.

Patented March 18th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides the machinery to run it. For right to use my Precipitator address O. O. BITNER, Spenceville, Nevada County, California.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by Dewey & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$1, (post paid.

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

MOREY & SPERRY,

No. 145 Broadway, - - NEW YORK.

come St.

Continued from page 21.

the Banker lode, towards the east line of Messrs. Smith & Kessler's claim, and bearing off in a southwesterly direction, was struck last month. A shaft sinking on it is 35 ft deep, following the vein which dips southward at the same angle as the main lode. The spur carries 18 inches of good ore. The Silver Bow mill has taken a trial contract of reducing 100 tons of Lexington ore. The main shaft of the Alice at date is 450 ft deep, and is going down very slowly through extremely hard granite. Thirty ft of sinking must yet be done to reach the 500-ft station and give the 10-ft sump required below it—a task which cannot be completed much before the first of next month. At the estimated rate of progress the ledge will be reached on the 500 level sometime in October. Shaft No. 2 of Late Acquisition lode is in 40 ft and on a 28-inch vein of good ore. The Clear Grit claim shows a 30-inch vein of high-grade ore following footwall, and low grade 10 ft in width towards the hanging wall. The ore mills about 30 ounces per ton.

OREGON.

JACKSONVILLE.—Times, July 4: The Grand Applegate company is now engaged in piling. The Squaw Lake company is still piling away with good effect. Hein Deneff, mining on Farmer's flat, last week, picked up two pieces of gold weighing nine ounces. The miners of Josephine county still have a fair supply of water, but some of them will commence cleaning up soon. James C. Thomas, headman and many others are now engaged in ground sluicing on Elliott creek, with fair prospects. The mining season has come to a close in Willow Springs district, the last miner, T. L. Beck, having suspended operations this week. The news from Silver creek is favorable, many of the miners there making good wages. Water is said to be falling at Briggs' creek since warm weather set in. Several of the miners on Sterling creek have just completed ground sluicing and are cleaning up. Kleinhammer & Co. among the number. The run has been a fair one. Beck Bros., on Big Applegate, have completed their ditch, which is about three miles long, and will commence active mining operations forthwith. Their ground is said to prospect well. They are to be complimented on their enterprise, which deserves success.

UTAH.

BINGHAM.—Tribune, July 4: Considerable work has been done to show up the vein in the Red River, situated near the old Spanish mine. At a depth of 100 ft the vein averages 25 ft, assaying from \$8 to \$15 in gold. A tunnel has been run about 75 ft, showing the vein about 18 ft wide, with similar assays to the last mentioned. Another tunnel has tapped the vein 200 ft from the mouth, which averages about 15 ft. Several drifts have also been run, all bearing evidence of a large deposit of ore in close proximity. This mine is on the gold belt. Jordan & Foley are working the Saturn. This mine has heretofore turned out considerable ore. MacManamy & Williams are working and piling out ore from the Gem. Recently they made a considerable shipment. Housholder & Jones' mine is called the Stewart No. 3, and is close beside the No. 1. It assays well and bears every evidence of a well-defined ledge. The Stewart company No. 2 have got their mill erected and anticipate being ready for operation in the course of three weeks. The building has been erected with a view to permanency and durability. The machinery is first-class and no expense has been omitted to make it a thorough success. Twenty stamps will be used, but no doubt they will have soon to enlarge their capacity. The mine is looking all that could be wished. Large bodies of high-grade ore are now in sight and further developments only prove the immense deposit of gold-bearing ore. The main tunnel is now in over 200 ft, and though not yet into the main ledge, some flattering assays have been made. From present indications the vein may be cut at any time and precipitate the owners into a huge deposit. The Stewart No. 1 still keeps up its reputation. Considerable improvement has lately been made in the mill in the way of new machinery, etc. The mine is looking as good as ever, and though a draw is made upon it of some 50 to 90 tons in 24 hours, it does not appear to have much effect in lessening the quantity of ore.

Professor Nordenskjöld.

In the latter part of May last, dispatches were received in San Francisco from Berlin, via New York, to the effect that Prof. Nordenskjöld, the Swedish explorer, had escaped from the Arctic ocean by the way of Behring's straits, and was on his way home, in the *Vega*, via Suez canal. Since that time no confirmatory reports have come to hand of his arrival in Japan, and many people have concluded that he was not seen upon the Siberian coast near the point the Esquimaux claim to have had a sight of his vessel. Late Stockholm papers, received at the office of the Alaska Fur Co., in this city, make clear what has heretofore been shrouded in mystery. The first dispatch is from Governor Schammarin, of Siberia, to a gentleman in St. Petersburg, dated at Jakutsk stating that he has letters from Nordenskjöld to the effect that on the 16th of September, 1878, he was caught in the ice in latitude 67° 3' north, longitude 171° 33' west, quite near to the shore, and that, as it was so early in the season, "he had hopes of getting through Behring straits, and reaching home, via Suez canal, before spring." This telegram has never been correctly given before, and in translating it what the Professor gives as a "hope," is rendered as a fact. The very latest in regard to the whereabouts of the *Vega* comes in the columns of a St. Petersburg paper. It is a dispatch from Governor Schammarin, dated Jakutsk, May 26th, stating he had a letter from Prof. Nordenskjöld, informing him that he had drifted down the coast some distance, and was, at the time of dispatching the messenger, located about 120 miles to the westward of East Cape. He had plenty of provisions and fuel, and had no fear but that he should work his way out safely with the breaking up of the ice this spring. This situation of the *Vega* confirmed the report brought to this port by Capt. Campbell, of the whaling bark *Norman*, which left St. Lawrence Bay on the 22d of October, who stated that a party of natives had just come in who said they had seen the spars of a ship near the shore at that point. It is a little singular that such a misconception of Governor Schammarin's first dispatch, as has been pointed out, should have misled the entire press. The probability is that the *Vega* will have worked her way out before the *Jeannette* arrives in the Arctic; and even now she may be on her way to Japan.—*Call*.

Up to the present time \$10,523,574 has been expended in the construction of the Brooklyn bridge.

The Great Western Quicksilver Mine.

EDITORS PRESS:—In your valuable paper of July 5th, I have read an article on the "Great Western Quicksilver Mine," by "B. W. C.," parts of which are liable to give your readers erroneous impressions.

He says: "Among the first, if not the first mine now being worked for mercury is the Great Western." Now it is not presumed your correspondent intended to convey the idea that this mine was the "first mine" being worked for mercury, but rather that it is the most valuable. Now, all who know the property will agree that it is a very valuable mine, but to say it is the "first" in value, or even "among the first" is scarcely nearer the fact than to say it is the first mine worked for mercury.

I find the Great Western has produced from 1875 to 1879 (about all her record) 18,930 flasks of quicksilver, an average of 4,732 flasks per annum. The New Almaden produced the same years 73,500 flasks, or an average of 18,375 flasks per annum. This mine has a record of 26 years, producing in that time 649,525 flasks, an average of 24,905 flasks per annum, and has produced in one year (1865) 47,193 flasks of mercury. It will not be questioned that this is a first-class mine. Of other California mines worthy of note may be mentioned the Guadalupe, which produced from 1875 to 1879, 26,384 flasks, or 6,596 flasks per annum; the Redington mine produced in the same four years 33,301 flasks, or 8,325 flasks per annum; the Sulphur Banks produced in 1876 to 1879, 28,510, or an average of 9,503 flasks per annum. These three mines are good second-class mines. If we should consider foreign mines, the Almaden of Spain is only worked about six months of the year and produces more mercury than the New Almaden, and could easily produce as much as all the California mines together.

Of the Great Western reduction works he says: "The principal extracting of quicksilver is done by one fine ore furnace of the capacity of 13 tons in 24 hours, and three coarse ore furnaces, each of a capacity of 35 tons in 24 hours. Of the coarse ore furnaces, two are Green's excellent furnaces—one of Coult's—patented in 1867 by Joseph Coult, then of Pope valley, but now of Texas. This furnace gives the best, easiest and cheapest results: does not cost one-fourth as much as the others—\$5,000 will put up two of them with condensers."

It has been asserted by one of our men of genius, that "a rose by any other name will smell as sweet," and he might have added that a furnace will do just as good work whether it is called "Green's excellent furnace," "Coult's," or any other name, but the construction of the furnace is the vital point. It may be unknown to your correspondent that "Green's excellent furnace" has been adjudged by a jury of 12 good and intelligent men to be a broad infringement of the Knox and Osborn patent, and that a heavy judgment is now standing against this mining company for this very infringement. But this learned correspondent informs your readers that one "Joseph Coult, then of Pope valley, but now in Texas, patented in 1867, a furnace." He did truly, and built it the same year, and set it up, and attempted to work it in the spring of 1868, and the attempt proved a most disastrous failure, the furnace never having produced a pound of quicksilver nor reduced a pound of cinnabar; but did reduce the inventor to a state of bankruptcy, after repeated alterations and additions, all of which were unsuccessful in improving the utterly worthless concern. The so-called "Coult" furnace built at the Great Western mine, has no resemblance in form, size, principal and manner of working, or in any other respect to the furnace patented by Joseph C. Coult in 1867, and no more resembles the furnace said Coult built in 1867-8, than does an Indian wigwam the palatial residence of "Nob Hill."

Your correspondent further states that all is "under the able management of the experienced mining engineer, Andrew Rocca. Mr. Rocca is a progressive and practical man, and has introduced many new, original and practical ideas in his various machines. His glass-roofed condensers are proving a perfect success." If your correspondent had looked upon the glass-roofed condensers closely, he would have seen that the "original and practical ideas" incorporated in those really excellent condensers, like the excellent furnaces, the invention of another man whose legal notice of his invention, with his name, is there conspicuously posted. I heartily endorse the "able management" of this mine by Mr. R., who took it with scarce a month's supply of ore in sight and has worked it up to its present capacity, and notwithstanding the very large amount of dead work done, has always made it pay much more than expenses, notwithstanding the very low price of quicksilver.

This happy condition of the company your correspondent attributes to "the flow of metal from the furnaces, that has not ceased for the last three years, yielding 500 to 600 flasks per month, or about 7,000 to 8,000 flasks per annum." These last statistics given by your correspondent will convince the most skeptical that although he may be unable to see a conspicuous notice posted on the "original and practical" machinery, he can see (nearly) double when he comes to counting flasks of quicksilver. But in describing the machinery for reducing the

fine ore, your correspondent sums up and makes all clear by stating that "the fine ore condenser uses a Livermore condenser," which lucid explanation clears up everything heretofore unexplained, and renders further comment superfluous. A WORKMAN.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

LAST CHANCE M. Co.—Object: To operate in Mono county. Capital, \$8,000,000. Directors—S. Luback, F. R. Bechtel, George Osgood, P. G. Childs and Robert Barton.

CALIFORNIA AND NEVADA MILL AND MINING Co.—Object: To operate in Napa county. Capital, \$10,000,000. Directors—Lewis Reynolds, A. G. Grosh, Alexander McKenzie, George Burgess and Thomas H. Reynolds.

CENTRAL M. Co.—Object: To operate in Bodie district. Capital, \$10,000,000. Directors—M. L. McDonald, W. H. Sharp, S. F. Gashwiler, L. Greenebaum and George W. Smiley.

Stockton Industry, Etc.

EDITORS PRESS:—With your permission and a space in your valuable columns, I will strive to give you a few items of the progress of this city and its leading manufacturing establishments, warehouses, Grangers' and Co-operative Unions, etc., which a short sojourn and limited acquaintance has placed within my reach.

The corporate limits of the city proper run between four and five miles; its streets run at right angles, dividing the city into blocks of 300 feet square. Stockton, with its immense warehouse facilities, makes successful bids for the farmers' grain, and stores it at small percentage. From a town of tents in 1849, it is now placed in the fifth rank as to population (14,000 to 15,000). As a commercial center Stockton has few rivals and no peers. She heads the list of the grain markets on the Pacific Coast. From the close proximity of the capacious warehouses to navigable water, its grain can readily be placed on board of steamers and sail g vessels, and in the bay of San Francisco be transferred to ships for the foreign and domestic market, thus saving the enormous wharf tax in San Francisco. The different warehouses have the following storage capacity: Farmer's Co-operative Union, 15,000 tons; Bagge's, 12,000 tons; Stockton, 20,000 tons; Farmers', 10,000 tons; Kallisher, 8,000 tons, and many other buildings used for storing grain during the season. The people of Stockton look healthy, wealthy and prosperous. The farmers as a class come to the city more or less, especially Saturdays, when they bring their wives, daughters and children and let their hard earned twenties take the wing. Many of the farmers have, by honest and upright industry, earned a competent living, and do not sell themselves or their families to want for the real comforts of this world. Their money is honestly come by, and they spend it freely for anything that will tend to their comfort and sold pleasure; neither do they forget or neglect the worthy poor. No man, woman or child leaves their door hungry or thirsty. These citizens of the soil are the ones that impart the great progress and prosperity to this, "the City of Windmills."

Matteon & Williamson,

Patentees and manufacturers of agricultural implements, corner Main and California streets. This house was established in 1852, at which time Mr. Matteon began to manufacture in this city. Thirteen years ago Mr. Williamson entered the firm, changing the name to Matteon & Williamson. This house manufactures, among other implements, Richards' improved header, canal and railroad plows, scrapers, the famous sulky iron gang plow, "American Chief," horse, bay and grain forks, threshing and stacking derricks, two-edged patent diamond plow, patent chisel cultivator, the horse single or sulky trow plow. This firm is now prepared to manufacture any and every article that is necessary in the agricultural implement line. With a force of 30 to 40 (including some of the most skillful mechanics on this side of the Rocky Mountains), leaves this institution excelled by none in workmanship and durability of their manufacture. During the past year they have erected a three-story brick building, where the blacksmith and wood work is done; recently they have completed a foundry, fronting on Aurora, bounded by Main, Market and Grant streets; working capacity, 60 square feet. About a week ago their first castings were turned out, with entire satisfaction to the proprietors. This enterprising firm has established a reputation which reaches far and wide; they fill orders from all parts of California, also from Oregon, Nevada, Washington Territory, Idaho, Montana, Nebraska, etc. Their improved workshops are among the finest on the Pacific Coast.

Masters' Feeder Works, and Regulating Windmills,

Corner California and Washington streets. Mr. E. J. Masters has been engaged for the last five years in manufacturing the "self-feeder" of a pattern invented by himself, which has been improved from time to time. Four years of practical experience has given it a standard reputation, until now it stands acknowledged head of the list for simplicity, effectiveness, light-running, durability and ease in putting on and taking off, for which testimonials too numerous to mention in these columns for want of space, can be furnished on application to the above works. Masters' self-regulating windmill, "Tempest," the most substantial self-regulator in the county and State. Its mechanism is of the simplest character, no weights, springs or levers are used in its construction, the solid or banded wheel employed so favorably known, renders it at once reliable and worthy the attention of our people. Masters' Universal Regulator, especially designed for regulating mill's constructed on different styles of turn-tables. This regulator is easily adjusted to old mills requiring the same. Parties desiring new mills or having old ones to repair and regulate, would do well to call at the above works.

Globe Iron Works,

Corner Commerce and Main streets. One of the earliest and most important manufacturing establishments of this city. Established in 1857 by E. J. Keep. Mr. John Cain is the present owner. Steam engines, machinery and castings of every description are manufactured in these works. A specialty is made of Root's rotary patent force-blast blowers for ventilating mines, and portable forges, Harsbarger's patent wheat scouers (smut mills), and all kinds of agricultural implements. Connected with the Globe Iron Works and under the same ownership is the

Stockton Agricultural Warehouse,

201 and 203 El Dorado street, near Main. Mr. John Oain is the successor to the "H. C. Shaw Plow Co.," which was incorporated December, 1875. There is on hand a large and full assorted stock of standard and late patents of mowers, headers, wagons, engines, etc.; in fact everything in the line of agricultural implements. They also own or control the patent and trade of the

Stockton gang plow and of the Stockton single-gear header, both in use throughout the State.

Grangers' Union of San Joaquin Valley.

This Union was incorporated May 14, 1874. Its members can be numbered among the most substantial men of Stockton, San Joaquin county and valley, most of whom are practical farmers. In its infancy they occupied a building on El Dorado street. October 1st, 1876, they moved into an elegant brick building, specially built for their own use. The building fronts on Main street, and has a large and fine entrance on California street. The floor contains 11,500 square feet. This Union does a large business and carries a heavy stock of goods, a full assortment of agricultural implements, iron, steel mechanical and blacksmiths' tools, wagons, hardware, rope, paints, oils, belting, etc., etc. It has everything that man and mind can imagine is kept in this popular and well managed establishment. The Grangers' Union is deservedly popular, well officered, ably managed, upright and prompt in all its dealings, and it is certain to be and remain a shining landmark in the rich and fertile San Joaquin valley. The originators of this institution may justly feel proud of their enterprise.

Pacific Agricultural Works.

Lafayette, between California and Sutter streets. The above works were established in 1875 by Messrs. G. Lissenden & Co. Both proprietors, Mr. Lissenden and Mr. H. C. Norris, are practical mechanics and supervise their shops personally. This establishment turns out all kinds of late improved agricultural implements. They also repair all kinds of farming machinery as well as manufacture the same. A specialty is made of the bulky plows "Star of California," the riding gang plow "Star of the West," and McCall's mammoth road scrapers. The celebrated header, thrasher and separator is manufactured by Lissenden & Co. This establishment gives employment to 15 or 20 men, and is doing a large and extensive business. Prompt attention, work of durability and fair dealing has given these gentlemen a far and wide reputation in their line of business.

Davis' Windmills.

For twenty years Mr. J. S. Davis has been engaged in manufacturing windmills of a patent invented by himself. He has from time to time made great improvements on these mills, until now it ranks first on this coast. The principal advantage possessed by Mr. Davis' mill is that the wind acts with equal force upon the whole length of the fan at all times. For the last eight years Mr. D. has made and sold an average of sixty mills per year. The celebrated Compound Hay Press is also manufactured by Mr. Davis. This press has a good reputation among farmers and gardeners. Prompt attention is given to repairing and regulating old as well as new windmills, hay presses, etc. Twenty-five years of practical experience give Mr. Davis great advantage in his line of business. His shops are situated west side of Commerce, between Main and Levee Sts. There are quite a number of manufacturers and retailers of notes that want of space will not allow me to give a detailed account of. Carriage manufacture of Wm. P. Miller, cor. California and Channel Sts.; carriage manufactory of M. P. Henderson, cor. Weber Avenue and California St.; planing mill of White & Thomas, Hunter, bet. Main and Market Sts.; chair factory of A. Wilder, Main St., cor. California; Stockton City Mill (saw), Sperry & Co.; Stockton Paper Mill; Stockton Woolen Mills; Pioneer Planing Mill; Pioneer (annery); City tannery; Lane's Mills (saw); Stockton furniture manufactory, H. S. Fickett & Co., proprietors. In conclusion, I will say that in view of the existence of these fruitful enterprises of progressiveness in this city, it must necessarily follow and be a guarantee to the outsider that to honest toil and staunch perseverance alone can this fruitful result be ascribed to.

Stockton, San Joaquin Co., Cal. J. W. H.

PROMPT AND SUCCESSFUL.—Messrs. Dewey & Co.—Gentlemen: Your Circular letter, 12th inst., informing me of successful termination of my application for patent received. Please accept thanks for the prompt and successful manner in which you have managed this business. Yours respectfully, J. H. CAVANAUGH Walla Walla, Dec. 24th.

How to STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicum. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

PRINTER'S PROOF PRESS, complete and in good working order, for sale at this office, at the low price of \$30. Call and see it.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FLETCHER, 415 Market St., second floor, S. F.

The Mechanics' Fair Daily.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the TENTH VOLUME of the MECHANICS' FAIR DAILY during the FOURTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Tuesday, August 5th, 1879.

It will be of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our nine previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our Coast.

DEWEY & CO., Publishers.

Office, MINING AND SCIENTIFIC PRESS, No. 202 Sansome street, N. E. corner Pine, San Francisco.

DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address, DEWEY & CO., 202 Sansome St., N. E. Cor. Pine, San Francisco.

Amusements.

CALIFORNIA THEATER. BARTON & LAWLER, Manager. BARTON HILL, Acting Manager.

AIMEE OPERA BOUFFE CO. Bush Street, above Kearny. Open every evening. Box office open from 9 A. M. to 10 P. M. Seats may be secured six days in advance.

Molera & Cebrian's System of Electric Lighting.

The electric light in itself is admitted to be superior to all the artificial lights known, and in many instances has been also the cheapest.

According to the testimony given by some of the most eminent scientists before the British Parliamentary Commission, appointed to investigate the merits of the electric light, it is called to supplant, in many cases, all other illuminants.

We have already given an account in one of our previous issues of the system of electrical illumination, by Molera & Cebrian, civil engineers in this city, and to-day we propose to explain in detail its application to the lighting of mines, for which it is specially adapted.

Its Application to the Lighting of Mines.

Two of the most prominent advantages of the electric light besides its superior kind of illuminating power, are the avoidance of explosions and fires, and the little influence it has upon the surrounding atmosphere, on account of the small quantity of heat it emits and of its not being fed by combustion.

These two advantages are of paramount importance in all kinds of mining works, where explosions are always fatal, and the heat and foul air of the mines themselves are so great.

In consequence, trials have been made in some collieries in England, and with satisfactory results; and we may expect at no distant future that the electric light will make the miner's work safer and more endurable, and consequently more profitable.

The general way of using the electric light seems not to be especially useful for mining work. The lamps are of too delicate a mechanism to be handled by miners generally; they must be enclosed in glass globes to prevent the electric arc being brought in contact with the gases in the air. But the system proposed lately by Molera & Cebrian is particularly adapted for these conditions as well as for others. Because in this system, neither the electric lamp nor the conductors need be in the places where the light is used. All the appliances to produce the electric arc may be kept in a small room above ground, and the light alone is transported to all places underground, and is applied to any particular point where most needed, and are particularly illustrated in Fig. 1, which represents the shaft and part of the working of a mine. *A* is the lamp and chamber of light, emitting several main beams of light, *A g*, *A B*, etc.; *m*, *n*, are the two wires connected to the generator of electricity. Fig. 3 shows on a large scale the chamber *A*. The electrodes form at *G*, the electric arc; *L*, *L*, *L*, are condensing lenses, which shape the light in beams of parallel rays; *H*, is a circular reflector to throw the downward light to the upper lens. This chamber, represented as a cube, may be of any other shape, and will emit as many such beams of light as faces, less one, it has, thus affording the way to convey light to different places far away; because, as it is well known, when light is condensed in parallel rays it can reach to long distances with a very small loss due to the absorption of the atmosphere. The vertical beam, *A g*, is intersected by a double reflector, *q*, that may be a totally reflecting prism, and it will change the beam, *A g*, in two horizontal beams, one of which, *q D*, is intersected at *c* and *D* by prisms or reflectors that divide it in two downward beams, *c l* and *D l*, to light the upper buildings of the shaft. These beams of light may be enclosed in tubes or pipes, to avoid their being intersected by dust or other foreign bodies; these pipes may be of any material, as they are not subjected to any special stress. These downward beams would strike the floor only, but they are intersected by lenses or reflectors, *l l*, which, according to their curvature and position, will disperse their light any desired way.

As instances thereof, we show in Figs. 4 and 5 two cases. In Fig. 4, *C C*, represents the

ceiling, *L l*, are two lenses, and, *r r*, a spherical reflector; the larger portion of the parallel beam of light passing through *l l* is spread in a diverging cone, and the other portion striking upon *r r* is distributed upon the ceiling and walls, as it may be required. Fig. 5 shows two lenses, *l l*, and a glass, *P P*, the inner cone of which serves as a reflector, and its outer side does the service of another diffusing lens, as represented; the sections of *P* and of the lenses are designed optically, so as not to waste the parallel beam of light, and distribute it according to the needs of the case. There will be two, three, or more different lenses near each outlet of light, each of which will give a cone of light of different width, by this means the light may be concentrated upon a writing desk or a large table, or it may be spread all over the floor, or still higher up the walls to the ceiling, as it may be needed. These lenses may be kept in a row,

beams of parallel rays reach their final destination they are intersected by the dispersing lenses, *l l*, to diffuse the light conveniently as represented.

In the underground workings the lenses may be used in connection with the adjustable reflector, *M*, of Fig. 2. It is a mirror or reflector attached to the spike, *S*, which is to secure it against the timbers or the earth. *L* is a lens that can be adjusted by means of a slide and screws, so as to receive the beams of parallel rays, *B B*, after it strikes the mirror, *M*. By the proper motion of mirror, *M*, and lens, *L*, the beams of light can be applied wherever needed; the lens, *L*, may be placed on top of *M* at the bottom or sides, according to the requirements of each case.

It will be seen that the reflector or prism, *B*, controls the light of the whole underground works, and that the prisms, *E F*, equally con-

trol the light of their respective galleries. If the reflector, *F*, is brought lower down it will leave its gallery in the dark, and will light a lower gallery or winze. Or if the prism, *E*, is removed, and prism, *F*, is made to slide so as to intersect the whole beam of light, *B F*, all the light before used in the upper gallery, will now be added to that employed in the second gallery.

Thus, the motions of the prisms and dispersing lenses accomplish the transportation of the light to and away from any point in the mine, and in amounts varying at will, as different cases may require. It will be readily seen from Fig. 1, that if all the prisms or reflecting lenses, and the tubes carrying the beams of light were placed along the floor joints and walls of a building that this system would also accomplish the lighting of several floors, and several rooms from a single source of light, *A*, and in a perfectly controllable manner. Therefore, this new system may be adopted to all kinds of uses. The losses inherent to this system are due to the loss of light when it is reflected or refracted, and also to the absorption of the atmosphere. All these have been calculated, and in no case do they reach 50% of the light at the lamp, *A*, (Fig. 1). All other systems of subdividing the electric light in small lights show losses of not less than 85% or 90%; therefore this new system must be cheaper than any other electric system. Besides, the other systems have a limit to the subdivision of the light, as their losses increase with the number of lights. But as the losses of this new system are independent of the number of small lights, the scope of its application must be very extended. This also allows for the new system, using a very powerful focus of light which has been found to be the cheapest.

As to economical advantages, it will be noticed that regulators or lamps are entirely dispensed with, and that attendance is consequently not required; a very great saving, both in prime cost and in running expenses.

Another important feature is, that the great expense and loss consequent upon the use of electrical conductors is entirely avoided, as the single lamp needed is located near the generator, permitting of the use of a short and thick conductor having practically no electrical resistance.

The light produced being small, the wasteful use of opalescent globes is suppressed.

A great advantage in having only a single lamp for a large system is, that a vacuum may be maintained in the chamber of light without difficulty, thereby preventing the rapid combustion of the carbon, which always occurs when the electric arc is maintained in air. The cost of the carbons, as well as the labor of replacing them, which, in the ordinary electric regulators, is something considerable, is entirely avoided.

Another great advantage of having only a single lamp, is the facility to use the quinine sulphate, the uranium glass, and the other substances that have the property of changing the blue, violet, and ultra-violet rays into white light, thus rendering visible and useful radiations which the eye could not perceive, and adding considerably to the brilliancy or intensity of the light.

As the electric lamp is kept away from the places that are lighted, this system well completely avoid the humming noise of the electric light, and the effect of producing nitrogenous vapors.

Besides the many different applications of this system, we wish to call attention to its adaptability to mining works of any description, to chemical factories, to powder works and magazines, and warehouses and other similar purposes, where the danger of ignition or producing explosions are so very great.

The invaluable feature that the steam engine and boiler, the dynamo-electric machine, the electric lamp and electric conductors may all be kept far away from the buildings, makes of this new system the only one that may be used in dangerous localities as cited above. In some of them light is altogether prohibited, and in others when it is used it raises the rates of fire insurance considerably. This last remark may be applied as well to the case of private and public buildings.

In the case of colleges, asylums, barracks and penitentiaries, where it is desirable that a single officer may have the control of the light, and where the great number of inmates makes the dangers from fire more liable to occur, this system also appears to be the only one that can be used with all safety.

Fig. 3 also represents a section of a new lamp on the float principle. The carbon rods are supported by pistons or floats in inclined tubes, *J*, which are connected at their lower ends by a horizontal tube communicating with the spring-acted bellows or cylinder, *K*. The tension of the spring that draws the top of the bellows down, may be changed by revolving the small windlass, *S*.

The top of the bellows is iron, and above it is supported an electro-magnet, which is in the electrical circuit. The carbons pass between conducting surfaces, and are also in the electrical circuit.

Continued on page 41.

MOLERA & CEBRIAN ELECTRIC LIGHTING APPLIED TO MINES.

and made to slide, by means of rollers, and cords or wires, which will be pulled more or less from the rooms, and the light regulates as easily as a gas key.

Turning again to Fig. 1 the horizontal main beam of light, *A B*, coming from the chamber of light, *A*, is intersected by the prism or reflector, *B*, which heads it totally into the shaft. At every gallery, winze, etc., proper reflectors are placed, such as *E F*, which, according to their size, will deflect portions of the vertical beam into their respective galleries. By a judicious use of reflectors or prisms the other main beams of the chamber, *A*, may be deflected and sent through the same shaft or to other shafts more or less distant. Also every one of the secondary beams, *E l*, *F l*, etc., may be deflected several times, upwardly, downwardly or laterally, so as to transport the light to any desired place in the workings. When these

control the light of their respective galleries. If the reflector, *F*, is brought lower down it will leave its gallery in the dark, and will light a lower gallery or winze. Or if the prism, *E*, is removed, and prism, *F*, is made to slide so as to intersect the whole beam of light, *B F*, all the light before used in the upper gallery, will now be added to that employed in the second gallery.

Thus, the motions of the prisms and dispersing lenses accomplish the transportation of the light to and away from any point in the mine, and in amounts varying at will, as different cases may require.

It will be readily seen from Fig. 1, that if all the prisms or reflecting lenses, and the tubes carrying the beams of light were placed along the floor joints and walls of a building that this system would also accomplish the lighting of several floors, and several rooms from a sin-

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Ede

Lumber, Mining and Tourists in Fresno County.

EDITORS PRESS:—Though crops in Fresno county are generally light, except on the few lands well wet by irrigation or mountain rains, other interests are giving considerable life to Madera, Berenda and Borden. Madera is not only the railroad terminus of the great lumber flume 52 miles long, which winds along Fresno River, and has brought millions of feet of timber from the sawmill seven miles northeast of Fresno Flats, but is the point of departure for Washburn's stages, which carry a large part of the Yosemite tourists, to visit that beautiful valley, some 400 having passed over this popular route from May 4th to July 4th. Again, large amounts of supplies are shipped from below to Madera and Borden for the

Lake Mining District, of Mono County
And intermediate mines of more or less recent development, around Fresno Flats as a center; also for the new mining districts along the upper San Joaquin, in the eastern edges of Fresno county, on the western slope of the highest ridges of the Sierras, and only from 10 to 15 miles east and northeast of Mammoth City. These supplies are hauled by freight teams to Fresno Flats and to still higher points, and are thence carried to their various destinations by pack trains, Mammoth City, the extreme point, being from 50 to 65 miles from Fresno Flats, according to various rough trails. To enable passengers to reach the Lake district and Bodie, by a quick route, a coach is run from Berenda twice a week (Tuesdays and Fridays) and these connect with

French's Saddle Train at Fresno Flats, The horseback ride being made to Mammoth City in a day and a half. By this route it is possible by hard riding, to make the trip from Mammoth City to San Francisco in 32 hours. The usual time from San Francisco to Mammoth City this way, is 22 hours to Fresno Flats, and 26 thence to Mammoth, or 48 hours, spend one night on cars and in Berenda, a second night at Beasore Meadows, some 20 miles east of Fresno Flats and 35 miles west of Mammoth. Fare by this route is \$14 to Berenda from San Francisco and return, and \$10 by stage to Fresno Flats and return, thence \$25 to Mammoth City and return, or about \$25 for the trip each way. The saddle train usually passes the only sawmill that is supplying lumber from

The Great Timber Belt

On the south side of the San Joaquin in Fresno county. This mill was erected in '73 and '74 at a cost, with the necessary roads, of about \$50,000. Sawing and the building of their flume commenced in June, '74, and the flume was completed in August, '76, requiring about 7,000,000 feet of lumber, costing between \$225,000 and \$250,000, according to the Secretary's books. It is the longest flume in the world, making a descent to Madera of over 4,400 feet, about one-third of this being made in the first five miles from the mill. The original company was known as the California Lumber Company. But the property changed hands last August, the present company, which is vigorously pushing the work ahead, being known as

The Madera Flume and Trading Co.

Juan Malarin is President, E. McLaughlin, Manager; remaining stockholders, C. T. Ryland and Return Roberts, all of San Jose. Wm. H. Thurman and James Dickinson, stockholders in the original company, now have a contract to cut, saw and pile the lumber at the mill. This mill runs by steam two five-foot circular saws and one gang edger, easily averaging 40,000 feet per day. They have turned out in the last five years, over 20,000,000 feet of lumber, and will saw from 5,000,000 to 6,000,000 feet in the next five months. From November to May they are obliged to stop operations on account of the heavy rains and snow, the latter falling sometimes to a depth of 10 feet there and on their timber claim, at altitudes varying from 4,800 to 6,000 feet.

The great timber belt of the Sierras is about 10 miles wide here, extending in all

Over 400 Miles,

From Kern river on the south into Oregon on the north, its general width varying from five to ten miles; altitude, from 4,000 to 6,000 feet. The sugar pines and firs here reach diameters from six to nine feet, and produce excellent lumber when carefully selected. The fencing and scantling made from the best firs is establishing a reputation equal to Oregon pine, Henry Miller having used 400,000 feet of fencing sawn from firs. He strongly endorses it as equal to Oregon pine, as Mr. Thurman informs me. Redwood posts are also shipped in large quantities by the flume. They are cut from the smaller members of the big-tree family (*Sequoia gigantea*). They are quite as lasting as those from the small redwood (*Sequoia sempervirens*). In the North and South grove of big trees, extending from two to three and one-half miles north of the Company's mill, are about 500 of these trees, varying in diameter from 4 to 30 feet, to say nothing of numerous small ones.

The Three Sisters

Are large, handsome trees in a straight line, the

outer ones not being more than 100 feet apart. The girth of the largest is nearly 100 feet. Their height varies from 250 to 350 feet. Fresno Flats is becoming an important station as the center of the gold mines of this county and a stopping point for teams, stages, pack trains and saddle trains. Its height above the sea is 3,150 feet, its climate is healthy and a fine type of the best mountain climate of California. It is surrounded by a number of very fine mountain ranches, where plenty of hay, potatoes, vegetables and fruit are produced. Some of them are provided with water for irrigation, which is very valuable in a season like this. This is especially true of the fine ranch of Wm. H. Crooks, settled by him in 1853, about six miles down the Fresno river from this point. His ditch and flume cost him about \$1,200, and his ditch now supplies water for the arastras of the valuable Enterprise mine, a mile from him. A future letter will give your readers some facts about mining interests of Fresno county.

J. W. A. W.

Fresno Flats, July 4th.

Virginia City.

EDITORS PRESS:—This mountain city, this city of great wealth, of vast enterprises, of un-resting activity; this city of the precious metals, of gold and silver inexhaustible, where the rattle of dumping rocks, the roar of cars, the whistle of the locomotive and the puffing of steam from crushing mills and vast hoisting works are ever heard; where men rest neither day or night, but the Sabbath is the same as Saturday; where toil, toil, toil, is the order of existence, and all the means of living are dependent upon those descending and ascending a half-mile perpendicular shaft daily into the solid earth; what pen can truthfully trace its features, and give to strangers, in the land of steady habits, a correct impression of its peculiarities?

The summit of Mt. Davidson, a prominent peak of an extended range, hangs loftily over the city on the west, while into its steep side the hand of man has dug terraced blocks and streets, so that as we entered on the ground floor of our lodging house, the Pacific, and passed to our cosy room in the back corner and looked out down from our window, lo! we were in the third story of the next street. Thus the buildings of the city rise one above the other on the steep mountain side like men on seats in a theater, but with an arena of the world a vast prospect to the east, where appear hills, peaks, ranges, gorges, valleys and plains, all treeless, grassless, worthless, as dried and dead as nature could well make them.

Yet there is gold here, and silver, which generations cannot exhaust for ages. The great Comstock vein extends in a clearly defined ledge full five miles in length, and may develop in miles beyond both ways. Side veins and branches are numerous, of varying richness, while the improving methods of working the rock are making more and more valuable all ledges bearing the precious metals, till those now really worthless may come to yield fine returns to those engaged in mining them.

We were more than ever before interested in discovering these possible developments outside of the real Comstock lead. We had the pleasure of an excursion visit with Mr. D. H. Jackson, large owner in and Superintendent of the North Bonanza and Flowery claim, nearly four miles north and east of Virginia. The claim is not in the direction of the Comstock lead, though surely this may bend and here appear in its genuine features. We went down its admirable incline over 500 feet, following the dip of the clearly defined vein, and out along its different levels, and everywhere the indications were excellent. We also went along on the outcropping ledge upon the surface, and saw the different prospecting openings, and everywhere the vein was clearly marked with walls smooth and distinct on each side as if made by the bands of men. The width of this vein is fully 120 feet, while exact measurement might make it much more. All this width of rock is metal bearing, while proper, not extra, selections have yielded from \$60 to over \$100 per ton. It is not known how far this body extends in length, yet for miles it is claimed waiting for the full developments of the Bonanza shaft.

Other veins like this elsewhere exist. One on the west of the city, higher up the mountain, seems to cross the Comstock to the north and is over 130 feet thick. We went into the tunnel prospecting this vein, over 1,000 feet, with its owner, Mr. Lyon, and though the vein is greatly broken and mixed, yet it may prove of much value in time. It is possible that the richness of the Sierra Nevada and Union claims is largely owing to their being located where this lead and the Comstock intersect.

The Comstock vein through Virginia and Gold Hill and as far as it has been worked, dips at an angle to the east, so that in sinking upon it over 2,000 feet, the works have been carried far to the east. Thus most of the companies have gone a quarter or a half mile eastward, and sunk new shafts either singly or in combinations to facilitate operations.

At the great depths of the shafts, some now over a half mile in perpendicular depth, the large amount of water encountered has compelled some once very paying companies to suspend work and expend all the energies of their machinery in pumping, waiting for better facilities for removing the water. This has been the

case with the Savage, which, for over two years, has been only pumping its water to keep it from destroying the mine. The desired better facilities have finally appeared, and the Suto tunnel, at length overcoming every difficulty, became fully available for use on the first day of July. So advantageous in this way, as also in others, is this tunnel proving, that in one day of operating through this tunnel the Savage was able to lower the water in its works 100 feet. This improvement may enable Virginia to regain its former activity, and again all its mines be shipping ore and declaring dividends.

There is only one really bad thing in the condition of affairs in this, as also in other, mining regions on the coast. Man, as a rational being, needs one day in seven as a time of rest from regular business toil. He needs it as really as he needs bread. Without such a day of rest, and of moral improvement, he may retain much of traditional or once customary, moral and intellectual character; yet gradually this surely wears away, and man sinks more and more downward in the scale of existence till he becomes a mere human automaton in labor, toiling for food and bodily comfort, like the tread-horse or mule in a mill. But he does not stop in his descent at this, for, as a being with a progressive character, he yet descends to lower depths, in debasing talk, associations and practice, a poor, abject, sensual being. It must be so without a day of rest, one in seven, a Sabbath for higher thought; nobler aspirations; purer, richer, happier attainments; becoming an intelligent, moral, immortal being. The provisions of Christianity are exactly united to man's wants and greatest possible good both now and forever.

S. V. B.

Mono County Mining Interests.—No. 2.

EDITORS PRESS:—I have just returned from an exploration and complete examination of the greatest, most extensively worked and oldest mine in the Bodie diggings, viz., the Standard. Being the oldest, a scrap of its history may not come amiss. Before Bodie had even started on its prosperous career, two Germans discovered the croppings of a small ledge where the Standard claim now is; this they worked with profit by means of an arastras; the ore on which they worked, however, was one of the thinnest of ledges, and although to them there was great profit, still the ore did not so much as form an approach to the quality now encountered, their insignificant ledge being soon abandoned by the present company. The first owners continued their work slowly downward until they came across a horse. With this obstruction they abandoned the downward work and commenced a drift; another horse was soon encountered and at this they began a drift on the opposite side of their shaft. Once again they ran across the inevitable obstruction, the horse, and, not even attempting to remove it, they gave up hope for further development. Discouraged at their poor success, they sold all to Seth and Daniel Cook and John F. Boyd of San Francisco. These with some others forming the company of present owners, \$67,500 was the amount paid by them for the property, and this was all realized at the end of the first month after it came into their possession. Since then all know the extent of their dividends, it being strictly a dividend-paying mine.

Under their management the name has been changed from Buiker Hill Bullion to Standard, the old ledge was allowed to rest and work began on the Standard ledge. A large force of competent men was employed. The Standard mill of 20 stamps was built and put in operation, and affairs assumed the aspect of continued and steady progress, exciting a lively interest in the camp which has increased to the present day.

Eight hours were spent by me in examining the works of the old and new Standard, and its extent totally prohibits the possibility of a complete description, but a rough sketch will be attempted, beginning with the old Standard.

The shaft or incline, properly termed, is run on the main or Standard ledge, which has an average dip to the 808 level of 45°, though approaching more a horizontal direction at the bottom, and becoming here nearly flat. Its thickness varies from one to fifteen feet in the thickest part, and is interrupted all the way down by numerous horres of syenite and porphyry. The first level we reach is 300 feet from the surface, and the strike of the ledge being north and south and the dip west, is drifted 450 feet north, 300 feet of which is stoped up 50 feet, and 450 feet south which is stoped upward 200 feet. On this level are several crosscuts and smaller drifts all yielding a rich ore, and the ledge varies considerable in width but little in quality. One hundred and fifty feet lower on the same incline, following the Standard ledge, we strike the 450 level; this we find drifted north 80 feet, and south clear to the Bodie line, 900 feet, the north drift being stoped up to the 300 level, and the south drift stoped up 100 feet. Another 100 feet lower and we strike the 550 level, the lowest level worked at present, all below this remaining to be worked by the new Standard shaft, which is located to strike this almost horizontal extension of the ledge and of parallel ledges at a reasonable depth. The level is drifted 500 feet south, 80 feet of which is stoped up 80 feet, and 60 feet north of which none is stoped. The mass of ore above the long drifts of this level remains *in situ*. On all these levels are crosscuts running

west and intersecting the ledges encountered, which run parallel to the Standard ledge. These ledges are the Brucs and the Burgess, each drifted and stoped out a little, but containing yet a "mountain" of rich ore, found and tested and waiting in nature's storehouse.

Proceeding to the new shaft we find arrangements for deep and exhaustive work. A three-compartment vertical shaft runs down 780 feet in all, water preventing further sinking for the present. Prospecting work has been carried on since the beginning. We find a 400 level where drifts and crosscuts expose three heavy veins to be stoped to the surface. Of these, one is the famous ledge of which we hear so much, whose thickness is in some places as much as 23 feet, a huge body of valuable ore. This I ascertained to be a fact, examining it closely and detecting large amounts of gold with the naked eye. Here then the ore has been found and fenced in, so to speak, with crosscuts and drifts—the game is cornered and the company has now but to play with it to their heart's content. It is not necessary for them to look farther, as there is now all they can manage with in easy reach; years and years of stamping and paying dividends will not exhaust their unlimited treasures. There is no speculation with this mine; nothing of the wildcat nature attached. The company is a responsible one, the Superintendent understands his business thoroughly, and where can we find a better millman than Dawley. Commendable, indeed, is the work performed by the following connected with this mine: Mr. Irwin, Superintendent; Mr. Hickey, foreman; Mr. Scowdon, mine surveyor, and Messrs. Gleason and McMillan who superintend the timbering and intimate manipulation of the work below ground.

A run through the Noonday mines reveals the following: The shafts, two in number, are south of the town on Silver hill; one of them represents Noonday proper and the other North Noonday. The former being the most developed, we will proceed to examine it first.

On the surface is found but the floating rock of a broken ledge. Descending a perpendicular shaft 50 feet we strike an incline the angle of which is 60°, and from this on the shaft follows the ledge of quartz, which varies between two and three and a half feet thick. Over this incline the bucket in which we ride slides clumsily along. After a total depth of 200 feet, we strike the bottom of the first drift. The total length of the drift, including both directions from the shaft, is now 280 feet; running north and south. This drift is covered by the remains of overband stoping to the extent of 40 feet up the ledge, and on the top of this debris is exposed a very good vein of quartz which assays about \$250, mostly silver. This stoping and filling in will be continued to the surface of the ground, running the ore down shoots which pass through the debris and discharge out the drift. From the 200 drift on each side are run crosscuts, the one to the east intersecting a poorly delineated vein, a few feet in, and the one to the west encountering a vein of good dimensions and fair condition, which is to be worked in the future.

From the drift, again, not in a continuation of the incline, there is a winze following the main ledge down 120 feet and occupied by an ordinary windlass manipulated by two men. Into the bucket we crawl again and down we slide. At the bottom we find our ledge made up of ribbon veins with a fair outlook and reasonable assays. The drift for this level is just begun, and the quartz between the drifts will be stoped out as above. By means of our bucket and a whim and two horses on top, we come again to the surface.

One hundred yards north of this shaft is the North Noonday shaft, down only 120 feet on a narrow ledge, but above, on which is now being erected machinery for sinking 2,000 feet, the most extensive in the camp. There are three good compartments to the shaft, and pressure drills are soon to be introduced which will bring about a speedy connection with the Noonday proper. R. D. Brevon is superintending the mines in the absence of Superintendent Fox. This company will soon put up a 30-stamp mill, and will then do a lively business. At present the Miners' five-stamp mill is crushing for them and disposes of but five tons of ore per day, \$12,000 being taken out of the Noonday last month.

The Booker mine has nearly finished a pump of enormous dimensions, which will raise water 1,500 feet. At present no ore is being taken out on this account. Considerable pride is taken in this, the first pump, in working order in the camp.

J. H. W.

Bodie, July 7th, 1879.

ORIGIN OF KEROSENE.—A Russian paper says that the farmers in the District of Kahlilanki (Poltava) have given up the use of kerosene lamps because this sort of oil (petroleum) comes from the decomposed part of Satan, who has been confined to rot beneath the mountains of Caucasus since he rebelled against the heavenly powers. The Boston *Journal of Chemistry* cites this to show the Russian superstitious sentiments, but no longer than one month ago an individual in Pennsylvania circulated a petition to the Legislature of that State to prohibit the sinking of any more oil wells, because the oil was needed to lubricate the axle of the earth, which was already beginning to grind through loss of oil. He obtained many signatures so it is said. An imagination sharpened by a constant diet of baked beans cannot be expected to find any superstition except in some foreign country.

MECHANICAL PROGRESS.

A Powerful Spectroscope.

In the young science of spectroscopy, as in others, an important element of progress is the improvement of instruments for dealing with the phenomena presented, and many minds are engaged on this. A new spectroscope of remarkable power has just been brought to the notice of the French Academy by M. Thollon. Its chief feature is the use of sulphide of carbon prisms, which are closed laterally, not by plates with parallel faces, but by prisms of the form of Amici's—i. e., having curved sides meeting at an angle, which, however, is much smaller than Amici's prism. The refracting angles of these prisms are in an opposite direction to that of the sulphide prism. Two of these compound prisms are substituted by M. Thollon for the simple prisms in a spectroscope, which he formerly described to the academy. Without going into further details, we may simply state that an enormous dispersion is obtained; with a magnifying power of 15 to 20 times, the spectrum has a length of 15 meters. The angular distance of the D lines of sodium is about 12', whereas that produced by M. Cassiot was only 3' 6". This instrument should throw considerable light on the structure of the spectrum, and M. Thollon has already noticed some interesting facts. The lines of sodium and magnesium present a dark nucleus passing into a nebulosity, which becomes gradually merged in the continuous spectrum. Many lines have been split up, and all that have been thus resolved have been found to belong to two different substances. One of the hydrogen lines presents a nebulosity without a nucleus. M. Thollon remarks on the magnificence of the spectrum of carbon from the electric arc, observed with the new instrument. The spectra of iron, copper, and magnesium in the same arc were also seen with admirable clearness and brilliancy. These new spectroscopes have been constructed for M. Thollon by the able optician, M. Laurent.

THE SPHYGMOGRAPH.—The sphygmograph is a recent application of the telephone, and is an instrument invented by Dr. Richardson, by which the movements of the arterial pulse are transmitted into loud telephonic sounds. In this apparatus the needle of a Pound's sphygmograph is made to traverse a metal or carbon plate which is connected with the zinc pole of a Leclanche cell. To the metal stem of the sphygmograph is then attached one terminal of the telephone, the other terminal of the telephone being connected with the opposite pole of the battery. When the whole is ready, the sphygmograph is brought into use as if a tracing were about to be taken, and when the pulsation of the needle from the pulse-strokes is secured, the needle, which previously was held back, is thrown over so as to make its point just touch the metal or carbon plate, and to traverse the plate to and fro with each pulsation. In so moving, three sounds—one long and two short—are given from the telephone, which sounds correspond with the first, second and third events of sphygmographic reading. In fact, the pulse talks telephonically, and so loudly that when two cells are used the sounds can be heard by an audience of several hundred people. By extending the telephone wires, the sounds can also be conveyed long distances, so that a physician in his consulting-room might listen to the heart or pulse of a patient lying in bed (speaking modestly as to distance) a mile or two away.

AN EFFECTIVE PLAN OF FIRE SIGNALS.—The admirable arrangement in this city for sending fire-alarms to the engine-houses and fire headquarters is nowhere seen to better advantage than in the Broadway store of Lord & Taylor, which was the first large establishment connected with the fire-alarm telegraph. At two points on each floor are placed electrical "buttons" inclosed in small wooden cases with glass fronts. If a fire occurs the duty of the watchman is to break the glass and push the "button," when an automatic machine on the fourth floor is immediately set in motion. This machine, being connected with the fire-department wires, communicates Lord & Taylor's special signal to headquarters. In a few seconds the alarm has been repeated at the nearest engine-house, and a steam engine is on its way to the fire. Should the first alarm miscarry, the gong-alarm, which is always sent to the engine-houses 15 seconds after the first signal, serves to designate the locality of the fire.—*New York Tribune*.

A SWISS EXHIBITION.—Switzerland has appointed the year 1881 for an international exhibition of watches, jewelry, snuff boxes and musical boxes—a display in which the ancient republic may well call the rest of the world to see what she can do. This project adds another illustration to the recent tendency of international exhibitions, especially in smaller countries, to run to specialties. This will be the first exhibition of the sort in Switzerland.

THE Scientific American wants some "wide-awake California boy" to invent a trap to catch that troublesome squirrel, the gopher. This is a personal affront. For every gopher in California there is a trap of some kind, the only difficulty is to persuade the gopher to go into it. Besides the gopher is not a squirrel. Has the *Scientific* tried salt on their tail?

ECONOMICAL STEAM ENGINE.—The Corliss engine at the French exhibition of 1878 consumed only one kilogramme (2.2 lb.) of coal per horse power per hour. A similar engine of 700 horse-power, constructed by M. Farcot, for the drainage at Asnières, consumes only six-tenths as much. M. Tresca, in recommending, on behalf of the committee of the French Academy, that the Montyon prize should be awarded to the inventor of this engine, stated three special advantages which it possessed. A form of construction which establishes a great firmness between the cylinder and the chief arbor, with the least consumption of material; the separation of the orifices of admission and emission, to the great advantage of the permanence of temperature in the steam at its entrance into the cylinder; and a system of distribution commanded by a central platform for the four openings by means of springs and came, which secure the opening and closing of the orifices. While claiming for Corliss the principle of separation between the orifices and conduits of admission and escape, the committee consider that Corliss' applications of the principle, the precision of action, and the economy of its engines entitled him to the Montyon prize of 1,000 francs, and the Academy awarded the prize accordingly.

INSTRUMENT OF RESUSCITATION.—A Frenchman has the credit of inventing an apparatus for aiding in the resuscitation of persons apparently drowned, or who from any other cause have been temporarily deprived of animation. It consists of a cylinder of sheet iron large enough to contain the body of an adult person. It is closed at one end, and the inanimate individual is inserted, feet foremost, in the receptacle as far as the neck, round which there is placed a padded diaphragm, fastened to the cylinder so as to be air-tight. An air pump, attached to an opening in the tube, creates a partial vacuum, and the outer atmosphere, by its own pressure, forces its way into the lungs by the mouth and nostrils, which are left exposed. By a reversed action of the pump the air is allowed to re-enter the cylinder, and respiration is thereby re-established. A glass plate inserted in the iron casing enables the operator to watch the movements of the chest, which rises and falls as in life with the working of the pump. The action may be repeated, it is stated, 18 times in a minute, an exact imitation of natural breathing being thus produced.

LIGHTING THE CAPITOL BY ELECTRICITY.—The arrangements for lighting the capitol building at Washington with a new electric light are nearly completed. The experiment has already been made in the Hall of the House of Representatives, and a single light placed on the front row of the reporters' gallery and over the Speaker's chair made the whole hall so light that print could be easily read at the points furthest from the burner. The plan is to place four lights in the hall, and it is now believed that they will be a very great improvement upon the present arrangement of gas burners. Three electric machines have been purchased under the appropriations for lighting the interior of the building, and it is in contemplation to place another in position for the purpose of supplying a light of vast power upon the top of the dome. It is claimed by the inventors that a burner can be constructed there which shall have a very appreciable effect upon a large area of the city. It is claimed that with the steam power of the heating and ventilating apparatus in each wing of the building, a dynamo-electric machine of 175,000 candle power can be run.

THE NEW TRANSATLANTIC CABLE.—The cable steamer, *Faraday*, left Millwall at an early hour on Monday, and during the forenoon was safely moored abreast of Messrs. Siemens' works at Charlton. The *Faraday* is a powerful steamer of 4,900 tons, built at Newcastle in 1874 for Messrs. Siemens, and designed specially for laying cables. In the course of the afternoon she was surrounded by barges; those on the outside supplying her bunkers with coal, and those next to shore being employed in passing the cable into the steamer's tanks. The new company, the official style of which is, "La Compagnie Française du Télégraphe de Paris à New York," has opened offices in London for the transaction of executive business at 100 and 101, Gresham house, Old Broad street. The *Faraday*, having on board the shore end and the Brest-Seilly section of the new cable, was cleared at the London Custom-house on Tuesday night for New York, and sailed for Brest the following morning. Her departure had been delayed, the wet weather having interfered with the work of coiling the cable in the bunkers.—*London Iron*, June 21st, 1879.

THE SOUTH AFRICAN CABLE.—The telegraphic cable to connect the European and Asiatic telegraphic systems with the Cape of Good Hope will be 4,000 miles long, extending from the Red Sea cable, of Aden around Cape Guardafui and along the east coast of Africa to Port Natal, where it made a junction with the present land line to Cape Town. The cable will be laid along the coast, the depth being moderate along that side of the continent and the facility for repairing possible breakages has been carefully ascertained. The cable will touch at Zanzibar, Mozambique, Sofala, Delagoa Bay, and thence to Durban as the submarine terminus, from which point the land telegraph becomes available to complete the circuit to Cape Town. The cost of construction and laying the cable is estimated at \$7,500,000. The line from Durban to Zanzibar is to be finished in July, and the whole cable by the middle of November.

SCIENTIFIC PROGRESS.

A New Theory of the Earth's Magnetic Poles.

From a study of the movement of the compass-needle producing declination at London, Mr. B. G. Jenkins, of the Royal Astronomical Society, has become convinced that the various vicissitudes of the needle during the last 300 years can best be explained by the supposition of a strong magnetic pole above the earth's surface, and revolving around the geographic north pole in about 500 years. He finds four magnetic poles, as maintained by Halley and Handsteen, to be necessary to explain satisfactorily all the phenomena of terrestrial magnetism, but he places these not in the earth, but in the atmosphere. These poles he regards as the free ends of as many broad magnetic belts, two extending from the vicinity of the north pole to the equator, the other two coming up from the south pole to meet them, the boreal magnetism of the northern belts uniting with the austral magnetism of the southern belts along the magnetic equator. These hands he believes to revolve at slow and unequal rates round the poles of the earth, producing secular variations.

It will be observed that Mr. Jenkins describes the magnetism of the northern hemisphere as "boreal." Contrary to the current theory, he holds that the north end of the compass-needle is a true north pole, and that the facts observed are, when properly understood, in full accord with the great magnetic truth that like poles repel and unlike poles attract.

After submitting the evidence in favor of this view, Mr. Jenkins argues in this wise: If the north end of the dipping needle is a south pole, its pointing to the ground in Boothia (where Sir James Ross located the earth's north magnetic pole) must be attributed to attraction. If it is attracted it is attracted by something either in the crust of the earth or at the center of the globe. If there is something in the earth's crust which attracts the needle in Boothia, it ought to attract the needle in London. But the needle in London is attracted neither to the crust at Boothia nor to the earth's center. The truth is, Mr. Jenkins believes, that the north pole of the needle pointed to the ground almost perpendicularly in Boothia because it was repelled by the true north magnetic pole in the atmosphere above that region when Sir James Ross was there 50 years ago.

Further evidence as to the existence of the alleged magnetic belts above the earth's surface is promised. Meantime, it is of the first importance, Mr. Jenkins thinks, that it should be clearly settled whether the magnetic pole remains in or above Boothia. According to his calculation it should now be in latitude 72°, longitude 115°, in Prince Albert land.—*Scientific American*.

THE NEEDED MOTOR.—The demand to which we have so often referred—a motor fitted for street railways—is felt in Europe, and the British Lords have been investigating the subject, and recommend the passage of a law permitting the use of such. They approve a locomotive worked by compressed air as more promising and desirable than any other, and advocate the use of steam engines in streets until a better discovery is made. The demand is for a simple power that can be attached to any car and that will draw it without fire. It is out of belief that science is stilled by so simple a demand. Study has not been given the problem. An insured reward would eventually discover it, and release countless horses, reduce fares, increase speed and avert injuries. We claim an unequalled ingenuity, and apply it to telephones and improve stoves and shoe-brushes. Here is a call for it, and every day that call grows more urgent. The wonder is that it has not been heeded, and that some slight machine or agent has not been found that will propel a car, a carriage, a sewing machine, a churn, turn a lathe, and be many men and horses in one. Let us have this instead of new designs for perpetual motion and new combinations for an elixir, and fortunes will repay the invention.—*North American*.

PETROLEUM AS FUEL.—Producers are gradually beginning to use petroleum as fuel under boilers, and they find it cheaper by far than coal. One large producer in the lower oil country, who is trying it, says that one barrel of oil a day with the gas from the wells, gives him sufficient fuel under a boiler that is pumping three wells. Before using petroleum, he was burning \$2 worth of coal a day. In the Bradford region, the petroleum burner is being introduced successfully, as well as in manufacturing establishments. But many hundred barrels per day more could be consumed if producers would but interest themselves in thus aiding the consumption of their product. Thousands of barrels daily could be used in this way, with a corresponding benefit to producers in better prices.—*Ec.*

THE EARTH BELONGS TO CHINA.—Dr. Schlie-mann has found Chinese vases and gauze linen on Trojan soil, dating 1,200 years before Christ. They were on this coast in the fifth century, and are now taking possession of it by right of prior discovery. Li-Fang-pao contends that the Hyperboreans were Chinamen, while here it is claimed that the Lepere are Chinamen.

Magnetizing Molten Iron.

In a letter to Dr. C. W. Siemens, and communicated by him to the British Society of Telegraphic Engineers, Mr. E. Chernoff records a very curious experiment: Believing that if it were possible to magnetize white cast iron a magnet of greater permanence than any made of steel would be obtained, Mr. Chernoff cast some white refined iron in a mold, surrounded by an electro-magnetic reel, along which a current was allowed to flow during the process of casting, so that the fluid metal became magnetic, and cooled under the influence of the magnetic current.

The result so far justified the expectation as to give a magnetized bar of white cast iron; but the form of the bar was unlike what was expected. While pouring the metal into the mold and until the metal set, Mr. Chernoff observed a singular agitation of the metal, which could not have proceeded from damp, as the mold was thoroughly dry. On cooling the bar proved to be hollow, the cavity being symmetrical and extending about two-thirds the length of the bar. The metal was thinnest just opposite the center of the reel, where it did not exceed the thickness of writing paper. The agitation of the metal in cooling is accounted for by the repulsion of the molten metal toward the poles of the magnet.

By casting under pressure it may be possible to obtain by this method extremely permanent and powerful magnets of white iron. Possibly also this experiment may lead to some useful modification of industrial processes for casting hollow cylinders without cores.

Telephone an Instrument of the Present.

There are said to be about 30,000 telephones now in service in this country, and only 500 in England—a fair sample of the greater quickness of the younger country to adopt new inventions. Prof. Wm. Henry Preece, an eminent English electrician, recently said he did not think that the telephone would be an instrument of the future, and be largely adopted by the public; "for although it had been largely adopted in America, we had not the same necessity for it, for we had a superabundance of messengers for all purpose, which the Americans had not."—*Ec.*

Perhaps not. We must, however, give Prof. P. credit for his foresight. The telephone, truly, will not be an instrument of the future, because in this country, at least, it is an instrument of the present, and as to England, refer to the following:

Twelve sets of telephones have been sent out to Sir Garnet Wolseley, for use at the seat of war in South Africa. The great advantage of the telephone over the telegraph, is that the General can carry on confidential talk with the officer at the district station, or a soldier can creep out toward the enemy's lines and whisper back the information as to position. A fine wire—the thinner the better—is all that is needed. This the soldier carries on a reel upon his back—a mile weighing only a few pounds. This will be the first time the telephone has been used as an instrument of warfare.

ARTIFICIAL SANDSTONE.—*Glaser's Annalen* contains a description of an improved method and apparatus for the manufacture of artificial sandstone. A thorough mixture of four to six parts of fine sand, and one part of slaked lime is exposed for about three days to a high temperature and a pressure of more than three atmospheres, causing the formation of a silicate of lime which acts as a cement, so that the mass, when cooled down to the ordinary temperature, hardens. This hardening process continues for some weeks by exposure to the air, so that finally a product is obtained which is as hard and solid as good sandstone. The apparatus consists of a tank, into which the mixture is filled, and in which it is beaten and stirred by a steam pipe, provided with a number of arms and rotated by belting or gearing. After the mixture has reached the proper temperature the steam is cut off, and a second vessel, inclosing the tank on all sides, is put into communication with the boiler. By this means the mass is heated for the period necessary. It is then run into a brick machine and shaped into the forms required. The process, it is claimed, effects great economy, especially for the manufacture of window sills, etc. The apparatus used is made large enough to produce 250 cubic feet of material in every charge—requiring, generally, three to four days.

GAS AND ELECTRICITY.—After a full survey of the field the *New York Times* concludes that gas companies have been driven from every stronghold except that of purely domestic illuminating by the electric light, and that they may be driven from that before the year 1879 closes. There are four electric lamps claiming to meet the conditions of subdivision, namely, Edison's, Holcombe's, Werdermann's and Fuller's, with one comprehensive method of subdivision, D'Ivernois', and one double-circuit generator, that of Mr. Keith. Neither of these has yet been submitted to test on a comprehensive scale, but all have done satisfactory work in the laboratory, and one of them, Werdermann's, has been tested in out-door experiments equivalent to street lighting. We have already referred to the fact that electricity and gas are not exclusives. A more perfect system of illumination will be introduced, and gas find other and more appropriate uses than as a means of illumination, as cooking, heating, etc.

now being pushed ahead by a double shift, has been driven 110 ft on the lode, at a level of but a few ft above the creek, which has exposed a very fine vein of copper ore, rich in gold. The pay streak is several ft in thickness, in places being scattered in bunches and small particles, and at other points there being a solid vein, which at one point is 21 inches thick. Copper pyrites is the predominating ore, with considerable gray copper accompanying it. The ore mills five ounces and upwards in gold per ton. The new shaft on the late discovery of the Ben

quantity of high-grade ore, and grows better with development. The Magrue tunnel, on the Little Minnie lode,

IDAHO

ITEMS.—Idaho City *World*, July 11: Messrs. Judd, Boyackin and George Dunningan have discovered a quartz mine on Slaughter creek, about a mile from the Harris road, in this county, that assays \$92 in silver and \$2.50 in gold per ton. The Sub Rosa mine has been started up on good ore. The mine looks splendid. The drifts show that the mine is more extensive than had been supposed, and the ore exceedingly rich. By sinking, other chutes have been discovered, with indications that they will continue to increase in richness with depth.

Idaho City *Advertiser*, July 12: A 20-stamp mill at Challis ready to run as soon as the road is finished. Capt. D. B. Varney & Co. commenced this week to sink a shaft on the Montana mine. Norton is running a double-bedded anastaxa on rich ore from the Norton mine. Large numbers of men have left Bonanza City to prospect the surrounding country.

MONTANA.

BUTTE ITEMS.—*Miner*, July 8: Mr. Sloss, of Sloss & Hammond, Silver Lake district, brought in 53 pounds of the bullion, the first clean-up for the season of their anastaxa working on Alturas ore. Messrs. Sloss & Hammond have been at work all winter developing their Silver Lake claims. At our last report the Alturas was 60 ft deep, at which depth the lode was five ft wide; but at present, at the foot of the 140-ft shaft, the lode is found to be a little

tom of the 140-ft shaft a level has lately been started toward the northeast, further to develop what has every appearance of being a most valuable mine. Mr. Britsch

Star, has commenced stoping from the western end of the Butte. He has already something over 500 tons of ore on the dump. Nearly a ton and a half of fine bullion was shipped from Butte last week. At this rate the shipment of 11 weeks would about equal in value a ton of pure gold.

NEW MEXICO.

ITEMS.—The chlorides and bromides of silver taken out in the Chloride District return an average of 70 ounces per ton. The mine has 13 shafts, around which are dumped hundreds of tons of rich ore.

NEW ZEALAND.

ITEMS.—*Thames Advertiser*, July 21: In the Red Queen, Johnstons and party have crushed a parcel of about 12 tons of general run, for the excellent return of 14 ounces 10 penny weight of melted gold. At Greymouth the Union Beach lodged 21 ounces of gold from five tons of quartz. At Preece's point a find of rich gold has been obtained. The Pride of Tokata is setting very rich

west of No. 4 winze are yielding good crushing ore. On the seaward side of the Moanatalari mine the lode on the No. 6 reef is two and one-half ft. thick and is similar to the

with mineral and iron pyrites. The lode on the 80 level, on No. 3 reef, is one ft thick of paying stuff. There is a growing impatience for dividends in the leading mines, and desperation possesses the mine managers.

OREGON.

JACKS—*Jackstone Times*, July 11: Thornton, Kincaid & Co. are doing well on Silver creek. They have picked up nuggets weighing \$80 and \$47, besides several smaller pieces. W. A. Johnson, an experienced miner, is opening a quartz claim in Josephine county and expects to commence crushing ore about the 1st of September. A partial clean-up was made the other day at the diggings of Kubil & Bolt, on Farris' gulch, which proved quite satisfactory. Several nuggets of quartz containing a large proportion of gold were picked up. Operations have been resumed and will be continued for several weeks yet. J. T. Layton, mining on Farris' gulch, made another clean-up a few days since after about \$1,000's run, which yielded 100 grains of gold or about \$1,000. Recent run

ports leave the impression that the richness of the Briggs' Creek mines has been exaggerated. The Silver Creek country promises better, as several good claims have been opened. Beck Bros., on Big Applegate, recently completed a ditch over two miles in length, and are engaged in ground sluicing. They expect to employ more scientific methods as they open their claim.

UTAH.

BRINOLAH.—Salt Lake *Tribune*, July 13: These mines are the West Mountain mining district, a sort of mining suburb to the mining city of Salt Lake. There has been but little work done on this group of claims, except what is necessary to keep the titles good, but there is no point in the district where the surface indications are more promising. The country rock is penetrated in various directions by porphyry dikes, and the metal-bearing lodes are, in most cases, true contact lodes between porphyry and quartzite. These facts give promise of large veins of good ore, as well as permanency to the depth. In the Stuart, Stuart No. 2, Edison, Susel and Bonum, extensive explorations made during the last eight months have exposed what may, without exaggeration, be denominated a mountain of gold ore; running from 20 to 300 ft in width, sufficient in sight to employ 200 teams continuously for from one to two years, with a fair prospect of huge reserves of mineral yet uncovered.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Martin White, July 8th, \$5,995.57; Northern Belle, July 9th, \$2,409.40; Eagle, July 9th, \$1,380; Con. Virginia, July 12th, \$25,492.37; Bodie, July 13th, \$11,700; Tiger, July 13th, \$17,000; Belle Isle, July 14th, \$39,000; Independence, July 14th, \$19,300; Eagle, July 9th, \$1,380; California, July 12th, \$46,658.39; Independence, July 14th, \$19,300; Alexander, July 10th, \$5,700; Indian Queen, July 7th, \$4,551.16; Northern Belle, July 7th, \$2,734.46; Standard, July 8th, \$40,795.04; Northern Belle, July 12th, \$4,397.84; Christy, July 14th, \$5,383; Hillside, July 16th, \$4,000; Martin White, July 13th, \$9,780.34.

GREAT BRITAIN is not the wealthiest country

on earth as has been supposed. Late estimates show that France is worth \$2,085,600,000 more than Great Britain.

THE cost to Russia of the war with Turkey amounted to £150,000,000, and the deaths in the Russian army numbered 200,000.

The Claims of Zoology.

(Read by W. N. LOCKINGTON before the San Francisco Academy of Sciences, Monday, December 23, 1878.)

In accordance with the constitution of this Academy, a "Zoological Section," composed of members specially interested in zoology, has been formed, and as we wish to gain the earnest support of all thinking men and women, I take the opportunity this evening to urge upon the members of this Academy, and through them upon the public generally the importance of this science, the science of animal life, to all of us who live and move and breathe in this beautiful world; for a beautiful world it is, in spite of the struggle we have to maintain life, in spite of human defects and passions, and in spite of all the dismal creeds that are the legitimate offspring of human spite and passions.

If the noblest study of mankind is man, then the noblest science must be that which includes man, must be zoology; the science of animal life; the science which tells us of our relationship with other organisms; which throws light upon the intricate workings of our complex structure by comparison of them with simpler structures, beginning with the lowest Protozoan that takes in nourishment without mouth or limbs or definite structure, passing upwards through all the varied range of hundreds of thousands of animal forms, and culminating at last in an intimate knowledge of that powerful and intelligent species which has obtained the mastery of so many of the powers of Nature, that it has the power for good or evil, of altering in many cases what would otherwise be the course of events.

Zoology is not, as many appear to think it, a mere dry science of technical names and descriptions; but is, to all those who can draw conclusions, to all whose eyes can take in a wide prospect, a beautiful and a poetical science, beautiful with the beauty of Truth, and poetical from its human interest, for it appeals directly to the sympathies and senses of mankind, and it is in such an appeal that the essence of all true poetry lies.

At the outset, it is true there is in this, as in every other subject worth knowing, a formidable array of technicalities to master. Each of all the countless forms of animal life must be docketed with a name, and a description must be written to enable others to identify the form when they find it. This is the first thing to be done, and without it our further progress would be stopped. Before we can build our mansion, we must be able to distinguish our materials otherwise we cannot arrange them in their places. But those who do this work, useful though it is, are but the hewers of wood and drawers of water to those who come after, unless they also can do higher work.

The whole of nature forms one grand design; it matters not, for our argument this evening, whether a supreme architect thought out that plan and superintends its execution, or whether the terms Nature and Universe being understood to include whatever has existence, the architect must himself be included in the design—in both cases the design is undeniable, and he who can most clearly see the proper place and real purport of the portions that come within his ken, is the really intelligent artificer, whether as a geologist, mineralogist or chemist, he works among inorganic substances; as a botanist or zoologist, he deals with life in its varied manifestations; or as an astronomer, his mind grasps the relations of worlds and systems.

The higher work, then, of zoology, consists in the knowledge of the structure and affinities of animals; of their place in the scale of nature; of their value in the economy of the world, of their relations to ourselves and to each other.

But for the proper accomplishment of this higher work another class of facts, different altogether from the mere docketing and describing of species, and of much more general interest, must be brought together.

The whole life-history of every creature must be studied from its first inception through all the stages of its growth in the egg, or within the body of its parent; through all the vicissitudes of its youth to adult age, and onward still to its inevitable decay and death; its environment, its food, the influence upon it of climate, of its enemies, of its rivals and of its friends, must be taken into account, and it will then be found that every creature, as we see it, is the result of a delicate adjustment between internal and external forces; between the hereditary tendencies of the stock from which it sprang, which tendencies are themselves the result of the environment of its ancestors, and the special influences brought to bear upon it during its own more or less brief existence.

Special conditions cause new forms to arise, this we see around us every day in our domestic animals, but to these variations which man himself has helped to bring about, or the causes of which we can clearly perceive, we give the names of breeds, races, or varieties; while to those the date and manner of whose origin is unknown to us, we give the name of species. For aught we know, some of the species found in a state of nature may be as recent as some of the races of our domestic animals, and a long-established race or variety is clearly on the road to be a species, and will become one, if it is well adapted to its environment.

To the class of facts I have just mentioned every earnest man, woman, ay, child old enough for school, may become a contributor.

Every human being who has eyes, and knows how to intelligently use them, who has a brain to think upon what he sees, and who will take

the trouble to jot down on paper every interesting fact he comes across, instead of trusting to memory, which is treacherous in the best of us, can aid in this work; and this is the aid which I venture to ask from all present, whether they are professional students of zoology or not; whether they join our section, or choose to remain outside.

Here then we have two classes of facts; on the one hand some individuals of a species have been technically described so that it may be identified; on the other, we have numerous isolated notes upon the localities frequented by it, the food it eats, the changes it undergoes through life, or to adapt itself to its surroundings, and upon its social habits.

At this point commences the higher, more difficult, but more interesting work, namely, to bring together these scattered facts so as to form a complete life-history, filling up the gaps in the record by systematic investigation, verifying, wherever possible, previous facts by repeated observation, and noting its varied relationships to other forms already known. In accomplishing this we are met with many practical difficulties, one of the greatest of which is the want of harmony and mutual appreciation that exists between those whose daily life is spent out of doors, and who have the best opportunities for the study of the habits, food and distribution of animals, and those who, confined in the city, but with abundant opportunities of studying recently killed or preserved specimens, take upon themselves the labor of describing and classifying. The former class require a more extended knowledge of animal life than is afforded by the narrow range of their daily life. To them, a robin is a robin, a woodcock a woodcock, every elongated fish an eel; they cannot perceive, until they really study the subject, that the same vernacular names are given to different animals in different localities, and that most animals have no name at all in the vernacular.

When an enthusiastic but un instructed observer of this class brings his observations to a professed student of zoology, he is apt to be offended when he finds that he either cannot make his interlocutor understand what animal he is talking about, or that his so-called eel is a lamprey, his "pike" a kind of carp, and his robin a relation of the thrush. The museum zoologist, on the other hand, though often unable to obtain from his own observation, facts of distribution, habits, etc., is too often discouraging and unsympathetic in his remarks to those who really, as far as their knowledge allowed, were accurate observers.

To bring together these two classes is one of the principal objects of this section. It is our hope to include among our number many ladies and gentlemen who have facilities for collecting and for observing the habits of animals not found alive on this little peninsula; to impart to them such information respecting what is done and what is not done, as shall prepare them to observe and to collect with method, and gradually to raise up a school of field naturalists, with eyes that can see intelligently.

It is also our hope to find, more especially among younger members, some who will take hold of some neglected branch, and make it their own, studying it in the field and in the cabinet; and it is our hope to be able, with the help of such workers, to arrive ere long at something like a general knowledge of at least the distribution, food, habits, and main peculiarities of external and internal structure of the animals, terrestrial, fresh-water and marine, of the Pacific slope of North America.

In as few words as possible I will endeavor to show you how little has yet been done toward this result, and to point out a few of the benefits to the human species that would result from a systematic study of our fauna.

The departments that have, not only on this coast, but in most parts of the world, received the greatest share of attention, have been the mammalia, our nearest relatives among the lower animals; the birds, to which men have ever been attracted by the beauty of some, the sweet notes of others, and the constant presence near us of many; the insects, interesting at once from their numbers, their varied colors, and their influence, in many cases injurious, upon us; and the mollusca, or at least their shells, which are so conspicuous and comparatively so easy to collect.

In all these departments most of the preliminary work has been done, the species have almost all been named and described, and their classification and relationships are tolerably defined. But how much remains to be known before we can say that we are possessed of the life-history of most of even these best known forms! Take even the mammalia, best known and fewest in species (on this coast) of all the groups. How many an interesting chapter might yet be written on the habits, distribution and food of the seals, dolphins and whales! The first two destroy our fish; is it not worth while to study their habits, that measures may be taken to check the too abundant increase of those species which are not in themselves useful to mankind? The fur seals are becoming scarcer; the elephant seal, once extensively taken for its oil, is almost extinct; the whale-fishery is often a failure. Would not a better knowledge of these creatures, disseminated among the classes who hunt and kill them, enable us to preserve them and even allow of their increase? Our rodents, many of them, from their inordinate increase, call for study from an economic point of view.

Were the life-history of every injurious beetle and butterfly fully known, the amount of damage they work to our crops of fruit and grain

could be greatly lessened, and even put an end to. So great have been the devastations of some of these insect enemies, which most decidedly were never made for our pleasure, but for their own, that some of the interior States have appointed commissions to find out a remedy. But this State has done nothing, though the locusts are sufficiently destructive, though various larvae destroy our apples and oranges, though aphides swarm on our vegetables, and even the dreaded phylloxera is attacking our vines.

Which of our native birds should most be fostered, for it is to our friends, the little birds, that we must look for aid against our countless insect enemies?

Our mollusks are good for something more than a place in the museum. Most of them are good for food, and very few of us have any notion of the countless numbers of individuals of some of the species of "clams," as every bivalve that is not an oyster or a mussel is commonly called, and of the extensive use that might be made of them for food.

The mollusca, moreover, form a large part of the food of many birds and fishes, and in this way also come into relation with our daily life.

The reptiles of this state are probably all described, although their habits require much elucidation; and the same may be said of the Batrachia, or frogs and salamanders. The curious metamorphoses through which this latter class pass are well known in a general manner, but no one has yet followed out the development of any of our Californian species, giving the date and duration of each step in the change from an aquatic to a terrestrial life.

Among the fishes doubtless many forms yet remain to be discovered; in fact, several have appeared in the markets this year that were not previously noticed. Here is a wide field of investigation, the time of spawning, the habits of the young; the laws which regulate the coming and going of our fishes, their comparative abundance at one season and their scarcity at another; their food, their favorite haunts, their range of variation, are in very few cases known; and as all these facts have a direct bearing on the supply of food for human use, they need prompt and full investigation.

Needful it is also to study their environment, so as to keep down their enemies, and to cultivate in bays, harbors and rivers those conditions of the water and of the bottom which are beneficial to them.

Probably the greater number of the higher crustacea (the *Decapoda*) have been described, but many species might be advantageously used as food which are now passed by as useless.

Among the lower crustacea little has been done; there are more unknown than known species, and probably most people would consider such small organisms as beneath the notice of practical men; yet these small creatures form a large part of the food of our fishes, and one of them, the *Limnoria*, comes holdly into notice as a wholesale destroyer of wharves and quays, biting the wood into dust, till the whole fabric crumbles. Who knows anything about our spiders? Few people probably, in this State. There lives in Sweden a man who could probably tell us more of the structure and habits of our spiders than any of us know.

Under the common name of "Vermes" or worms, are grouped numerous classes of animals having little resemblance to each other, but incapable of being classed with Vertebrates, Mollusca or Arthropoda. Some of these groups appear to form the starting points from which one or other of the higher sub-kingdoms may very possibly have been derived.

Some of them inhabit the ocean, roaming free or building for themselves curiously-formed tubes; others live in fresh water or in damp places in the ground, and yet others find their proper dwelling inside of some animal, in the intestinal canal, in the muscles, even in the brain. These internal worms often inhabit two or three different animals at different stages of their life; passing from a herbivorous creature to the carnivorous animal that devours it; or they lurk in the water, ready to develop within the unfortunate mammal or bird that drinks it; and many of these forms are proper parasites of man, while others live when by accident transferred to him.

Who can say, therefore, that the worms, some of which foreshadow higher forms, and others torment and even kill our domestic animals, while others do not spare man himself, are not worthy of study?

But I must draw towards a conclusion, and can only mention the echinoderms, or sea-urchins, star-fishes, crinoids, etc.; interesting on account of their peculiarities of form and structure, some used as food by certain nationalities; and many, now no longer living, forming with their dead bodies an important portion of the rocky crust of our globe; and the coelenterata, or corals and jelly-fishes, the lowest animal forms possessed of definite tissues, creatures consisting of nothing but stomach, skin and feelers, with sometimes the first rudiments of eyes and nerves, yet possessed of marvelous beauty, and building, some of them, those massive coral reefs, monuments of buried islands, which put to shame the noblest structures raised by man.

Below all these lie the countless forms of the Porifera or sponges and the Protozoa, or one-celled organisms, the Foraminifera that, though but structureless jelly, form wondrous shells which help to build up the strata of our earth; the Radiolarians with their network of glassy needles, and the Infusoria that swarm in the waters of every clime.

In view of all this, who can think of zoology

as a dry science, who in his senses can think it a useless one?

Above all other problems in interest to a living being, is the problem of life, and it is by the intelligent study of life alone that the slightest light can be thrown upon this, the most difficult of all problems. For thousands of years men have been trying to reason out the nature of things by *a priori* argument, forming theories and creeds of more or less plausibility, without ever referring to the real Book of Life, the Universe itself.

This book of life is no closed book, no locked and guarded secret like the pretty secrets of suspicious or dangerous men, but an open volume written in large lettering, for all to read who have the will; but man has for ages placed his foot upon this sacred volume, and, despising its contents, because in his mistaken vanity he has believed himself to be higher and nobler than anything it contained, has looked for information from unknown realms, of whose very existence he has no certain knowledge, and can at most only say, "They may exist," or "I trust they may exist."

The Eclipse of 1880.

California, amidst all of its golden blessings, is to receive the full benefit of the grand total eclipse of the sun which will occur on the 11th of January next. All of its sublimity is to be bestowed upon our State, and this fact may excite the landable jealousy of other States to provide a similar exhibition in the near future. The field is open and the moon and sun not controlled by any human monopoly. Scientific men and amateurs are already making preparations to visit us, and we should be prepared to receive them, with moderation as to pecuniary expectations. State character is as good and valuable as individual character, and besides the world at large holds to the doctrine of Montesquieu, that when the State possesses a had disposition it is because the people who compose it are wrongly disposed.

Inyo county lies almost exactly upon the central line of totality, and this county, as shown by the *Independent*, offers advantages unexcelled by any other county in this State or any other kingdom. First, clouds, even in winter, especially in January, rarely obscure the heavens; and, second, we have the highest and yet most accessible peaks (and many of them) in the United States. The highest of them is Mount Whitney, 15,200 feet above the sea level, to the very top of which observers can ride on horseback—harring an accidental snow storm to prevent. But in any event, the snow-belt is never but a few miles in width at any time, since it is but a few miles from the mountain summit to the valley, where snow never, or "hardly ever," falls. There are dozens of other peaks in sight, some much easier of access, and several nearly as tall as Mount Whitney. But in view of the risks of clouds on the high Sierras, the surest place for good observation is from the summit of the Inyo range, say 20 miles eastward of the high peaks of the Sierras, therefore not far enough from the central line of totality to be of consequence. The towns of Darwin and Cerro Gordo, and the Indian Queen mill, a hundred miles to the northward, are all in this range, and all well suited for points of observation. There are fewer cloudy days or hours to intercept a heavenly view from that range than from any other in this State. Its peaks reach an altitude of about 9,000 feet. The atmosphere on this range is, as before intimated, almost universally perfectly clear, even when the summits of the Sierras, but a few miles distant and the lands west thereof, are all buried in haze or clouds.

Of course San Francisco would be the rendezvous for all parties, and other localities selected. So let us be prepared to do our share in the scientific features accompanying a total eclipse. Scientific men of this State are acquiring a world-wide reputation, and they should maintain it. We have capital, and to spare, for improvements, and more of it might be devoted to scientific pursuits with profit to the capitalist and benefit to humanity.

A BURIED FOREST.—It has been recently discovered that an oak forest lies buried in the valley of the Fulda, near Rosenburg, Hesse-Cassel, Germany, at a depth of from six to nine feet below the surface. The wood flourished at a very remote period. The greater number of the trees discovered were in good preservation; but, owing to the action of the water through unnumbered ages, they have become thoroughly black in color; they have also become very hard and close, so that they would be good material for carving and ornamental cabinet work. Some of the trees are of great size; one taken out of a gravelly portion of the bed opposite the village of Baumbach, and since sent to the Geological Museum at Berlin, was 69 feet long, nearly five feet in diameter near the root, and about 35 inches at the top. Even larger specimens have been found. It is reported that the furniture and fittings of the Geological Museum at Marburg are to be made from this long buried timber. It is not yet decided whether these buried oaks belong to a species still existing or to an extinct one.

EVERY adult man has 1,400 square feet of lungs; rather, the mucous membrane lining the air cells of his lungs, if spread upon a smooth, plain surface, would cover an extent of 1,400 square feet.

THE ENGINEER.

The Railway of the Future.

Comparatively novel methods for improving railway operations in various ways, appear to be under serious consideration. One of these directions was probably indicated in a speech delivered by Mr. Edmund Smith, one of the vice-presidents of the Pennsylvania railroad, at a banquet given by the Wholesale Grocers' Association of Philadelphia in Long Branch a few weeks ago. After referring to the marked improvements which have resulted from the introduction of steel rails and the increase of the load of freight cars from one ton per wheel to five tons, he said: "Shall we go on to improve and develop the system in the future as in the past? There is no reason why we should not. I venture the opinion that the day is not far distant when our main lines of railway will be illuminated at night by the electric light, and other and greater improvements will keep pace with the spirit of the age."

The same subject was discussed more at length in a paper recently contributed by Sir Edward Watkin to the *London Times*. He suggests that there "is no reason why the railway machine should not be so improved as to far more than double the industrial forces." To promote this result he advocates a great increase of the rate of speed of all passenger and freight trains, accompanied with facilities which would enable any passenger "who chooses, to utilize undisturbed the flying hours of the accelerated railway train." He estimates the time now consumed by the English traveling public in railway journeys at 200,000,000 hours, which, at the low rate of sixpence per hour, is worth £5,000,000, or the capitalized sum of £125,000,000, and he contends that appliances might be devised which would enable many travelers to use advantageously time that is now lost. He also suggests "the use of stations for purposes of business, of deposit, of merchandise, and of banking." He also strongly advocates a great increase in the average rates of speed, contending that "if one train can go 60 miles an hour with given loads others can do the same."

Sir Edward declares that what is wanted is, equality of speed and the means of passing stations of second importance instead of stopping at them. As regards any railway with traffic enough in costly regions of property we could establish, if need be, a second story. The former is a question of the equalization of the power of the engine and of the provision of a kind of carriage for goods, minerals, and cattle which could safely run at maximum velocity. The essentials of this latter are the best material, proper springs, oil-boxes, spring-buffers, four-feet or four-feet-six-inch wheels. The railway loader would have to learn his business of storage for speed. The increase and equalization of speed would double the time-saving at present affected by railways, and then let me ask the reader to realize the new power of production, the new power of competition, the new lengthening of life resulting."

AN OLD ENGINE.—A venerable relic of past engineering skill has been presented by the Earl of Lonsdale to the Patent Office Museum, South Kensington. This is a specimen of Heslop's winding and pumping engine, a patent for which, numbered 1,760, was taken out in the year 1790. Heslop's engine, one of the immediate predecessors of James Watt's invention, was considered in the days of our great grandfathers to be an almost perfect machine, being superior to the atmospheric engine of Newcomen, even as improved by Smeaton. The present engine has been at work in the neighborhood of Whitehaven for 73 years, having been erected at Kell's pit for raising coal about 1795, afterwards removed to Castlerigg pit, and thence to Wreath pit in 1837. At the latter place it not only lifted coal out of the mine, but worked a pump till last summer, when it was brought to London. The engine now at South Kensington is the last survivor of its race.

JAPANESE INDUSTRIES.—Deposits of petroleum have long been known to exist in Japan, but they were not, until recently, utilized, that people not being able to refine it. Having learned how to prepare it for burning, they have gone extensively into the business and will now be likely to make enough for their own use, thereby somewhat restricting the outlet for the American article. They have also started in to work their gold, silver, and copper mines, which for ages had been much neglected, though they are quite numerous and with the aid of improved machinery and methods can probably be worked with profit.

TEST FOR MERCURIAL VAPORS.—M. Merget recommends paper steeped in the ammoniacal solution of nitrate of silver, or in chloride of palladium, as reagents for mercurial vapors much more sensitive than gold foil. This test paper is very sensitive; a slip of sheet-copper plunged into a liquid containing one part of mercury in 10,000 remained bright after immersion, but if exposed to the ammoniacal nitrate of silver paper it occasioned a characteristic black spot.

The explosion of giant powder at Bodie was not perceived by the miners below ground, although the effect was tremendous on the surface.

USEFUL INFORMATION.

CAN A STEAM PIPE SET FIRE TO WOOD?—At the Crescent Steel Works in this city, a steam pipe two and one-half inches in diameter, carrying 90 to 100 pounds pressure, was laid underground about three years ago, encased in common pine boards about one inch thick. A few days since occasion was had to dig up the pipe, and the whole length of the wooded drain was found to be charred, and apparently burnt, about three-fourths of the thickness of the wood, the other fourth being partially rotted. The whole inside of the drain was turned to charcoal, with here and there spots of white ashes, showing the ignition had actually taken place. It seems probable that if the casing had not been excluded from the air by the earth covering, it would have blazed and been entirely consumed. It is generally believed that a steam pipe cannot set fire to wood, but this case seems to prove the contrary, and it may explain the origin of many mysterious fires. It indicates at least that care should be taken to prevent the close proximity of easily combustible material to steam pipes carrying a high pressure of steam. The temperature of steam due to a pressure of 100 pounds per square inch is about 337° Fahr.—*American Manufacturer*.

FLAVORING MEAT ON FOOT.—M. Moulcar, a noted agriculturist in France, advocates the flavoring of meat on foot, by appropriate feeding. He says that by flavoring the food of cattle, sheep, pigs and poultry, their flesh may be rendered much more agreeable to the palate than it often is. He is substantially right, for reasoning by contraries, we know that rabbits, quail, deer, etc., which feed and browse upon the artemisia and bitter seeds have a disagreeable flavor when eaten. Any flavor may be given the meat—mint, anise, thyme, etc., and several tastes may be given the meat, or a compound flavor be added by a variety of flavors of any selection. For invalids particularly, or for epicurean palates, the common meaty flavor can be modified in flavor to suit the palate, and the aversion to healthy, nutritious meat be overcome by a delicious conglomeration of sweet flavors. We hope to see the experiment tried in our State.

CAMPFOL BALLS.—Clarify a pound of mutton suet, and add to it three pounds of spermaceti, two of white wax, and one of gum camphor, cut into very small pieces. Melt these together with gentle heat, and stir until the camphor is dissolved; then pour it into molds. Frequent application of this emollient will prevent disagreeable roughness of the hands. Should they become chapped, a most effectual but inconvenient way of healing them is to wrap them in wet cloths with an outside bandage of flannel, first making a free application of the camphor balls. This treatment will soften and whiten the roughest skin, and it is also an excellent application in chronic rheumatism.—*Boston Journal of Chemistry*.

MANUFACTURE OF JAM IN AN ENGLISH TOWN. The motto of the Kentish town of Maidstone might well be "jam satis," for the making of jam is becoming one of its chief industries. One manufacturer alone, Mr. E. Steer, is reported as boiling up last season the astounding mass of 2,000 tons. This extraordinary quantity was chiefly made up of black and red currants, raspberries, damsons and plums; and to contain it seven large loads of jars were required, in sizes capable of holding from 4 to 14 pounds each.—*Etc.* [Let California fruit growers and canners make a note of this jam business. The English palate has a weakness for jam, and we ought certainly to be able to divide the honors with Mr. Steer.]

TO STOP LEAKS IN BARGES.—There are only about ten inches of water in the rivers about Pittsburgh, and the acres of coal boats and barges are getting very dry, and the seams are opening. When a coal craft is leaky a keg of dry sawdust, packed tight, is lowered into the water in front of the barge. At a point beneath the surface a sudden jar dislodges the sawdust, which floats up and lodges against the bottom and sides of the boat. Wherever a crevice admits water the sawdust is drawn in, sticks there, and swelling, makes a water-tight job that will last long enough to save the boat and cargo.

A NEW PAINT FOR PLASTERED WALLS.—An excellent paint for ceilings and walls has been invented by a German named Reissig. It prevents the formation of fungi, and renders the surfaces coated with it impermeable to fluids or vapors, and capable of being washed down with boiling water without injury. This paint is a solution of about 50 grammes of stearate of soda in 1,000 grammes of spirit having a specific gravity of 66. The solution may be given any desired tint by the use of the aniline dyes, or of other, ultramarine or such other colors as are not subject to decomposition.

MILDEW IN CANVAS SAILS.—To take mildew out of canvas sails, saturate the spots with a solution of calcium hypochlorite (bleaching powder) in cold water or vinegar; using plenty of cold water afterwards to rinse. Mildew in canvas sails may be prevented by treating the sails with a strong aqueous solution of alum, or sugar of lead.

ENAMEL FOR "PORCELAIN" KETTLES.—Grind together 100 parts of powdered calcined diatom (or white quartz sand, free from iron), 50 parts of calcined borax (borax glass), and 20 parts of kaolin (white potter's clay), pass this mixture through an 80-mesh sieve, and mix it with water to form a thin paste. Lins the clean vessel with this and let it dry slowly. Then fuse together 125 parts of white glass, 25 of borax, and 20 of soda; powder when cold, and make into a thin paste with four parts of soda and a sufficient quantity of hot water. Cover the first coating with this, and, after thoroughly drying, heat in a muffle until the glazing has properly fused.

A BRICK-LINED TANK.—The *Metal Worker* says that some years since Prof. Chandler, President of the New York Board of Health, built a tank which was not only serviceable but cheap. He had made of stout plank a large box carefully braced, and lined it with bricks, each one of which was dipped in melted coal-tar just before it was laid in place, the coal-tar serving instead of mortar. A thin coat of this substance was spread over the inside, which made the tank thoroughly water-tight.

CEMENT FOR BISULPHIDE PRISMS.—A good cement to fasten the sides of bisulphide of carbon prisms is made of a mixture of good glue and concentrated glycerine, the composition used for making rollers in printing presses.

GOOD HEALTH.

Sight and Reading.

M. Javel, in a recent lecture, tries to answer the question, "Why is reading a specially fatiguing exercise?" and also suggests some remedies for this fatigue. First, M. Javel says reading requires an absolutely permanent application of the eyesight, resulting in a permanent tension of the organ, which may be measured by the amount of fatigue or by the production of permanent myopia; secondly, books are printed in black on a white ground. The eye is thus in presence of the most absolute contrast which can be imagined. The third peculiarity lies in the arrangement of the characters in horizontal lines, over which run our eyes.

If we maintain, during reading, a perfect immobility of the book and the head, the printed lines are applied successively to the same parts of the retina, while the interspaces, more bright, also affect certain regions of the retina, always the same. There must result from this a fatigue analogous to that which we experience when we make experiments in "accidental images," and physicists will admit that there is nothing more disastrous for the sight than the prolonged contemplation of these images. Lastly, and most important of all, in M. Javel's estimation, is the continual variation of the distance of the eye from the point of fixation on the book. A simple calculation demonstrates that the accommodation of the eye to the page undergoes a distinct variation in proportion as the eye passes from the beginning to the end of each line, and that this variation is all the greater in proportion to the nearness of the book to the eye and the length of the line.

As to the rule which M. Javel inculcates in order that the injurious effects of reading may be avoided, with reference to the permanent application of the eyes, he counsels to avoid excess, to take notes in reading, to stop in order to reflect, or even roll a cigarette; but not to go on reading for hours on end without stopping. As to the contrast between the white of the paper and the black characters, various experiments have been made in the introduction of colored papers. M. Javel advises the adoption of a slightly-yellow tint. But the nature of the yellow to be used is not a matter of indifference; he would desire a yellow resulting from the absence of the blue rays, analogous to that of paper made from a wood paste, and which is often mistakenly corrected by the addition of an ultra-marine blue, which produces gray, and not white. M. Javel has been led to this conclusion both from practical observation and also theoretically from the relation which must exist between the two eyes and the colors of the spectrum.

His third advice is to give preference to small volumes which can be held in the hand, which obviates the necessity of the book being kept fixed in one place, and the fatigue resulting from accidental images. Lastly, M. Javel advises the avoidance of too long lines, and, therefore, he prefers small volumes, and for the same reason those journals which are printed in narrow columns. Of course every one knows that it is exceedingly injurious to read with insufficient light, or to read too small print, and other common rules.

M. Javel concludes by protesting against an invidious assertion which has recently been made "in a neighboring country" (Germany no doubt), according to which the degree of civilization of a people is proportional to the number of the short-sighted shown to exist by statistics; the extreme economy of light, the abuse of reading to the detriment of reflection and the observation of real facts, the employment of Gothic characters and of a too broad column for books and journals, are the conditions which M. Javel believes lead to myopia, especially if successive generation have been subjected to these injurious influences.—*London Times*.

The Effects of Drinking Coffee.

This brown beverage prepared from the berry, improperly so-called, of the *Levaut* leads more than half the world vanquished in its triumphal train, mocking the energetic and barbarous means employed to combat it and check its march. It has found innumerable friends and willing subjects, not only in Europe and Africa, but in America. In the Orient and in Middle Germany it has become the national drink, England and Russia alone preferring the tea-canister to the coffee-pot. The reason of this extended popularity, and the physiological action of coffee have not hitherto been clearly understood. Prof. C. Binz, an investigator to whom we are indebted for a explanation of the action of alcohol, has also rendered a service by carefully examining the active constituents of coffee, namely, caffeine, the empyreumatic substances produced during the burning, and its potash salts.

Moderate doses of caffeine produce an increase of bodily temperature without any symptoms of illness being perceived at the same time. Large doses, which caused perceptible stiffness of the muscles, disquiet, and flow of saliva, were attended with increase of temperature, reaching a maximum in one or two hours, and then decreasing somewhat, but frequently lasting for hours. This action of caffeine renders it an antidote to that of alcohol, and it is employed to counteract the effects of opium also. Experiments made upon dogs show that it is able to check the fall in temperature caused by alcohol, and to produce a continued wakefulness in place of the stupefaction of opium.

Empyreumatic compounds found in burning, and called in France *caféon*, consisting chiefly of burned oils and bitter principles, also contribute to the action of coffee upon the system. To test their action when isolated from the caffeine, Binz employed the aromatic distillate of a strong decoction of coffee, which smells strongly of coffee. It caused increased activity of the heart with more frequent breathing, and reduced the pressure of the blood.

The increase of temperature assigned to caffeine, by Binz, can result only from an increased decomposition and consumption of material. For most coffee drinkers, the real effects of the drink are due solely to the moderate excitement of these oils.

HEARING AND HOW TO KEEP IT.—Lindsay & Blackiston, 25 South Sixth street, Philadelphia, have published a valuable work under the above title. The book is Vol. I. of a series of American Health Primers edited by W. W. Keen, M. D. From the mass of information contained in it we learn that the ear should not be tampered with, sweet oil and other greasy substances should never be dropped into the ear; they make it heavy, sticky and cloggy. The oil soon becomes rancid and affords a fit soil for the growth of a fungus which may entirely destroy the hearing. Punctures should be avoided both in eye and ear, for they are apt to induce proud flesh. Care should be taken of the bodily comfort, warmth, etc., and the ears protected against cold drafts and other changes. Great care also should be taken not to pull the ears of children, or "box" their ears, a practice which may endanger the hearing in after life. If the ear should become affected through any cause a simple treatment should be adopted. If the ear runs, it should not be stopped up with cotton or any other substance. The matter must be allowed free egress, and the syringe should be gently used with lukewarm water. The great delicacy of the ear requires the gentlest manipulation, and all the nostrums advertised to drop in it, or sponges to scrub it out, must be avoided. As to the eye bright colors and pleasant objects are grateful, so to the ear sweet music, pleasant company, etc., are beneficial. Brightness of nature and cheerfulness of character have more to do with the preservation of health than is dreamed of. The above book may be found at A. L. Bancroft's.

ABSINTHE IN FRANCE.—According to the deposition of Dr. Blenck, absinthe causes 60% of the cases of insanity in France. The *liqueur* is produced by the distillation of alcohol with wormwood (*Artemisia vulgaris*), either pure or mixed with other herbs. Several are used for the purpose of varying the flavor,—for instance, the anise (*Anisum*), the angelica (*Angelica archangelica*), etc. M. Magnan, in a series of experiments on animals, has found that the poisonous properties of absinthe are much greater than of any other spirituous liquor, even alcohol. The leading members of the medical profession in France are strongly opposed to teetotalism. They not only prescribe alcohol in various cases, but recommend the use of such stimulants to their patients in moderation; but they unanimously condemn absinthe.

EUCALYPTUS IN A COLD OF THE HEAD.—Prof. Strambio, in a note in an Italian medical journal, says that notwithstanding the failure of all remedies hitherto recommended for the immediate cure of a cold, he wishes to communicate to the profession the great success he has found attending a new one in his own person, and to ask them to test its efficacy. He found prolonged mastication and swallowing of a dried leaf or two of the *Eucalyptus globulus* almost immediately liberated him from all the effects of a severe cold.

The Week.

There is not much comfort to be derived from the aspect of the mining business, if we regard it in the sole light of a speculation. But considering the results of the past week from a substantial and legitimate standpoint, values are finding their proper position in the financial scale. When Daniel Webster was censured for making the law his profession, when that profession was already so crowded, he used to reply "there is room enough at the top." There certainly is room for mining interests at the top of the scale, but there undoubtedly is considerable "debris" from the base of the ladder all the way up. Now an enormously rich strike is made successively in our various mining regions, while the irrepressible Yaqui Indian turns up with chunks of silver weighing 3,500 pounds found in Sonora. So great is the richness of the reported "finds" that our fears sometimes lead us to believe that the market for precious metals will be immediately glutted. But modified statements soon come in and our fears are relieved. The mining novelist finds scope for the full display of his imagination in our gold fields, as well as the sensational writer in other fields of human affairs.

To offset all of these glittering accounts, it is a relief to come down to the hard fact, that the Comstock has piled upon its shareholders \$2,000,000 to be paid within the next 60 days, and that \$500,000 more will be called for before the month is out. No dividend is promised as an offset; in fact a dividend and an assessment would be an anomaly. Just now the "bonanza" seems to be in the pockets of the stockholders. Three-fourths of this assessment money will come from Pacific Coasters and about one-fourth from Eastern investors. In the case of the Bullion and Exchequer, where prospecting has been a failure down to the 2500 level, except the stock words "favorable indications," the enormous amount demanded from stockholders to dig another hole in the ground is plainly pronounced a swindle. The managers of the Comstock seem to be vieing with each other to get all the money they can.

The Evils of Big Surface Ore Finds.

The averment that the finding of extremely valuable deposits of the precious metals on or near the surface is a matter to be deprecated will, to most ears, sound wholly paradoxical. By the masses, and even by some educated miners, the mere suggestion of such an idea will be regarded as an economic heresy, if not the vagary of a diseased imagination. To the inconsiderate nothing in the prosecution of this industry seems so desirable as the finding of just such bodies of ore under just such conditions. Why, they argue, is it not better to come upon them right in the croppings than to be obliged to go delving after them in the dark bowels of the earth? And at first thought their reasoning seems sound enough. *A priori* we would all incline to say the same thing. But unfortunately our experience contradicts the conclusion. These great surface strikes have not always proven happy events, all things considered. On the contrary, the most of them have been productive of infinite mischief. Where they have been or promised to be of great magnitude at the start, they have almost invariably led to so much premature outlay, disappointment and loss as might justly cause us to deprecate their occurrence. Almost every noted discovery of this kind that has happened in our day has been attended with so much that was evil as to warrant its being characterized as a real misfortune.

Nor can we except from this remark the finding of the pioneer bonanza on the Comstock lode, the typical discovery of this new departure in vein mining, when the business, laying aside its slow and conservative ways, took on more vehement and extreme modes of procedure. It has been too much the custom to laud this discovery as an event of unmixed good. That it gave an impetus to this branch of mining and led to a more early and rapid exploration of the great interior basin and other outlying mineral districts, than would otherwise have ensued, is no doubt true. That it has encouraged the investment of capital in this industry and hastened improvements in everything pertaining to ore extraction and reduction, cannot be denied; yet there is much to set off such total benefits resulting from this Comstock ore find. If it tended to hasten exploration and perfect improvements, it evoked at the same time a spirit of reckless adventure, wild speculation and improvident expenditure. If it helped to increase bullion production and accelerate the settlement of these inland regions, it done much also towards creating a feeling of general unrest, and not a little towards dehauching the public conscience. And it may be, too, that we have overrated the value of this discovery as a promoter of mining and the early settling up of the countries mentioned.

Long before the occurrence of the special strike that, through a general carelessness, has been suffered to pass as the first discovery of the Comstock lode, placer mining was being carried on at several points in western Utah, now the State of Nevada. Not only so, but for more than a year prior to that event quartz mining was being diligently prosecuted at Gold Hill by a class of hardy, patient pioneers, and with a success that would no doubt have led to the wide extension and the permanent establishment of that business on the "Eastern slope," had this bonanza discovery never occurred. And, in this latter event, who shall say that this industry would not have experienced a more healthful, though perhaps a slower growth than it has since done? What of disaster and loss might not have been avoided had this pursuit been left to advance into these desert regions by slower stages and surer methods than those since employed to force it forward? What of wasted means and wasted lives might have been saved had mining been extended into these distant fields in a temperate and judicious manner instead of being prematurely jammed in under this Comstock craze. In view of the excesses and follies into which this discovery betrayed us, it is to be regarded as hardly less than a public calamity.

Starting out under this high-pressure action, and measuring our expectations by a standard so dangerous, we spent with a lavish hand and rushed things with a fatal speed from the first. An army of prospectors hurried over the Sierra, every one of whom proposed to find for himself a veritable Comstock, and would be content with nothing less. Having located everything in the vicinity of their great sampler these silver seekers began their search after similar lodes elsewhere, spreading thence over the country in every direction. The first big thing to reward their efforts was the Esmeralda find, followed in quick succession by the Humboldt, the Reese River, and the Silver Mountain discoveries, all deemed at the time of the first importance. After an interval of a few years (none of them without their minor excitements) came the White Pine lasso, and then the Panamint bubble, the last of these hasty and hurtful movements, unless Leadville, and perhaps other of these Colorado mining camps, shall require to be added to the list, of which there is a danger.

While none of these precipitate movements reached any large success, all but one or two, resulted in signal failure, and yet rich mineral deposits occurred on or near the surface in nearly all these centers of attraction. The ruly ore found in the very croppings of the Reese River lodes was a marvel of beauty and richness, and it is highly probable that there never was a finer body of ore of like size uncovered than the

Eberhardt bonanza at White Pine. And yet no two districts in Nevada, taken as a whole, have a more deplorable history than these. Reese River is a country of deserted camps, and White Pine a synonym of financial disaster.

A few miles to the west of White Pine is situated the flourishing town of Eureka. When the former was discovered Eureka was a hamlet peopled by a score of miners preparing to work the argentiferous galena found at that point. The superior attractions of Treasure Hill soon depopulated this infant settlement, the base, lead-bearing ores of the latter appearing poor indeed beside the rich carbonates and sulphurets of its neighbor. But bow stands the case to-day? White Pine is a desolation and a ruin! Her towns and her great mills have gone to decay or disappeared altogether. Her population has left and her bullion shipments have shrunk to almost nothing, her mining interests having well-nigh suffered total extinction. But her whilom rival, which she once so emptied of its inhabitants, lives and prospers. The base-metal hamlet has grown into a populous city, surrounded by great mines and sustained by a profitable and permanent industry. It ships every year bullion to the value of eight or ten millions, with the prospect of increasing the amount largely hereafter.

Far across the deserts, in another part of Nevada, lies the Columbus district. This, like Eureka, has a dull record but a very good one. There never was any stamped to Columbus, there being no "specimen" deposits here to create an excitement and rush in the adventurous. The early population was scant and came in slowly, the ledges, which made only a fair showing of medium grade ore, having been opened, little by little, and without the aid of much capital. No more mills were put up than the mines called for, and these were at first of small capacity. But they were all kept running, and the bullion flow that commenced with the very inception of the camp having grown to large proportions, has been kept up ever since. Many other examples of this kind might be cited, all tending to show that the most stable and prosperous of our mining camps are those in which there have been found no bonanzas or extremely high-grade ores on or near the surface, and which, in the absence of turmoil and excitement, have been settled and developed slowly. Here, as elsewhere in nature, the tardy growths have been the most healthful, satisfactory and enduring, teaching that these great top strikes are not always the things most to be desired, and admonishing all of the necessity of patience and perseverance in mining.

We can scarcely recall a mining district that was opened with so much blare and crash but has since suffered collapse, or been been wholly wiped out of existence. The turmoil and racket that have attended the early settlement of mining camps have generally been in the inverse ratio of their staying qualities, and we can almost believe that there would to-day have been less in the history of the Comstock lode, with all its vast production of bullion, that we might wish to recall had its wealth been revealed to the world in some less sudden and striking way. Who shall say that it would not have been better for the interests of mining as well as the interests of morality had that revelation come through the slow approaches of these pioneer miners, operating their arastras and other primitive appliances at Gold Hill instead of being blurted out in a way that threw it into the hands of the reckless and avaricious, to be used so largely for speculative purposes. It is very likely that much might have been saved had we started silver mining on a lower plane, went somewhat slower and observed a little more caution after we entered upon it. Let us not become too much excited over these fine ore exhibits at the start, nor attach undue importance to those mineral lodes that, like vain men, carry most of their wealth on their backs.

A National Convention of Bullion Producers.

The New York *Bullion* advocates a national convention of bullion producers, and, being a New York journal is intensely New York, as, of course, it ought to be, it says: "A three days convention in Cooper Institute of prospectors, miners and ore reducers from every gold and silver district in the Union would have for its audience the representative capital and business activity of the entire East." We are strongly in favor of any convention that will have for its object the improvement and development of our mining interests, whether that object be attained by means of Eastern capital or our own. We have commercial relations with New York, and merchants of that city take pains to encourage whatever will increase their income and endeavor to attract investments. Our relations with the East are exceedingly amicable. The financial balance is against us and in favor of New York. We have gold and silver to barter for goods, and the balance against us is provided for thereby. Although largely dependent upon the product of our mines for the maintenance of commercial activity, we must not overlook the fact that mechanical and productive industries are necessary to our permanent supremacy on this coast.

Mr. Gladstone's prediction that the commercial supremacy of the world must ultimately pass from the United Kingdom to the United States, strikes conviction to every man who

devotes any thought to the subject. In the torrent of commercial disaster, which lately swept over the world, America was the only nation prepared for it, and our system the only one to recover its balance and tone, while other nations, with the exception of France, are still prostrate.

England, dependent solely upon a mechanical and agricultural development, not having the material at command naturally enough overlooked the enormous character of the precious treasures buried in the American continent, and thus, the United States rivaling her in competing mechanical and agricultural industries, left her far behind in the struggle for the crown by being able to supply the world with money from bullion obtained in our own territory, and the scepter is now within our grasp. History but repeats itself in nations as well as in the affairs of men. The Roman empire, weighed down with precious metals and stones, became demoralized and perished. Later the Spanish kingdom glutted with wealth fell into decay, from which it has never recovered. So England, the commercial dictator of the world heretofore in mechanics and agriculture, must fall, and her own statesmen admit the fact.

The United States, however, by dividing her industries, developing mechanical and agricultural facilities and powers, and, at the same time, drawing bullion for money—the world's standard of exchange—from her own territory must take the lead among nations, and maintain her supremacy until the mines within her border cease to produce the coveted precious metals.

This dual character of our commercial capacity exhibited practically on this coast has caused the Eastern States to pour a stream of capital in this direction. And although mining as a business cannot be compared to any other business because there is no *quid pro quo*, but a constant diminution of value without possibility of restoration, there is enough yet, when combined with other industries, to enable us to maintain our position as a vast commercial center.

Perhaps these and other questions of moment will properly come before such a convention as has been proposed, and although our private preference would suggest San Francisco as the place of meeting, because the workings of our mining system could be practically investigated; yet we wish to favor the project and not disturb any unanimity that should exist by any sentiment that might be construed into sectional jealousy. It is proposed to hold the convention in December or January next, and the following subjects for discussion have already been suggested, viz:

Prevention of litigation; processes of reduction compared; capital of mining stock companies; mine reports; condition and prospects of our gold and silver deposits; debit and credit sides of our bullion production; gold and silver mines as national banks; progress in mining machinery; mining schools; a national mining bureau. To which we beg to add the subjects that may be derived from our remarks above.

What is Legitimate Mining?

The avalanche of abuse heaped upon our mining stock business by the friends of legitimate industries, has so nearly smothered us that we can only reply between gasps for breath. Why cannot our mining stock business be done legitimately? The profundity of the question could be better determined if the words "as it is in the East" were added, but crocodiles reserve some tears in their lachrymal glands. The mining business is always legitimate.

When there is wealth of ore, gold or silver in the mine whose stock is put upon the market, and there is an earnest endeavor to develop the same by working it up into bullion, then that mining business is carried on legitimately, even if the expectations of the company should be realized only in part. When, however, a mere shaft, drift or ordinary hole in the ground, salted with a few selected specimens is foisted upon the market by some impetuous sellers, the matter assumes the character of a swindle, it does not attain to the dignity of a business. The disaster attending stock speculation have been mainly brought about by the greedy delusions of the people themselves. "Why do you break the Sabbath by selling milk?" said a preacher whose pitcher had just been filled. "Why do you break the Sabbath by buying it?" retorted the man of calcium hydrate; and the query of the moralistic reformer as to the sinfulness of stock gambling is fully answered by the retort of "why do you invest, whether on a margin or otherwise." We have always advocated the idea that stock gambling was not only wrong *per se*, but disastrous to the commercial interests and integrity of the community, and we have never neglected an opportunity to appeal to the common sense of the individual to investigate, and never permit himself to be misled by a fabulous return from a small investment. This is the criterion. Money yields only a certain return, say 10% or 12% per annum, all above that is unhealthy, and the higher you get in the scale of return the nearer you get to downright robbery and swindling. Be satisfied with moderate returns. A poor man with \$100 cannot become rich all at once even in mines, and to speculate in stocks with it is equivalent to depositing it on the faro table. To prevent stock gambling we must begin aright and show up individually the solid companies and the wildcat.

Molera & Cebrian's System of Electric Lighting.

Continued from page 33.

cal circuit. The tubes, *J*, as well the horizontal tube and the bellows, are filled with a suitable liquid. As the current passes from one carbon point to another the core of the electro-magnet becomes magnetized and attracts the head of the bellows with more or less force, maintaining a uniform light by governing the distance between the carbons by displacing the liquid in the tubes and throwing the pistons or floats up or down, according to the strength of the current.

Should the current cease the spring draws down the head of the bellows and the points of the carbons touch. When the current is too strong, the top of the bellows is attracted upward, and the carbons separate.

Figs. 6 and 7 show a table-lamp or candlestick, built on the same principle. *N* is a partially elastic chamber containing the liquid. *P* is either a float or a piston, holding a carbon rod or electrode, *U*; *U'* is the other electrode, held fast by an arm, *U''*; *S* and *T* are two electro-magnets and a spring, having adjusting screws.

By changing the tension of the spring *T*, this lamp may operate as an incandescent lamp, as a voltaic arc, or as a flashing lamp. If that tension is sufficiently strong, or no magnet, *S*, is used, *U* will always be pressing against *U'* like a Werdermann candle. But if that tension is weaker, and *S* comes into play, it will operate either as the lamp, or by flashes, according to whether *P* is a float or piston.

The upper carbon, *U'*, is a horizontal cylinder, having a circular motion, and a side motion along its axis, imparted by a screw, *U''*; by properly attending to said motions, *U'* may be worn away evenly, and be useful until nearly worn out. This is an advantage upon the top carbon of the Werdermann candle, which is worn out at a single point. This lamp would also work with different shapes of carbon, *U'*.

It will be noticed, the great similarity between this lamp and the Higgins lamp, first presented at the *conversations* of the Inst. of C. E., the 26th of last May, at the South Kensington Museum, London. Take away in Figs. 13 and 14, the magnets, *S* and *T*, spring, *T*, and float or piston, *P*, and there it is, the Higgins incandescent lamp. It gave very good satisfaction; it was pronounced the best table light yet exhibited; but it was not free from the element of uncertainty—it flickered yet, and it went out for a few seconds, apparently without cause. It is to be expected that the controlling or regulating apparatus, *S*, *S*, *T*, *f*, of Figs. 13 and 14 will prevent the objections raised to the Higgins lamps.

The applications for patents on these lamps, in which the principle of the Higgins lamp is also included, were filed by Molera & Cebrian since July, 1878, in the United States, and in January, 1879, in England.

The main characteristics of those lamps are: Their simplicity, the total absence of delicate mechanisms and the independence of the two carbons or electrodes. In the greater part of the regulators, when the negative carbon advances a distance, the positive carbon is made to advance twice as much, by the aid of some mechanism. But in these lamps each electrode moves on steadily, independently of the other one, and independently of the ratio between their wear.

Practical Estimate of Electric Light.

To conclude, we will place herein an estimate of the cost of setting this system in a mine, taking as basis the actual prices of the machines as they are now constructed.

For the expenses we will not take into consideration the cost of steam engine, as that power is already a fixture of the mine; therefore the expenses will be as follows:

One Brush machine, No. 7.....	\$2,300
Two lamps (one reserve).....	200
One chamber of light, or projector.....	1,000
Prisms and lenses.....	200
Electric fittings, etc.....	200
Setting up the machinery.....	200
Total.....	\$4,100

In the running expenses, the item of the power will also be left out, as it has to be expended, in any case, for the mining works:

Per. hr.	
Cost of carbon points (in the case of 18 large lamps fed by one machine it is found to be 45c per hour; in the case of a single lamp it will be a great deal less—but to make allowances let it be called 45c).....	45c
Attendance to electrical and optical apparatus.....	30c
Ten per cent. per year upon cost of outfit to cover interest of capital (taking 24 hours daily use).....	41c
Ten per cent. per year upon cost of outfit for wear and tear (same condit.).....	42c
Total expenses per hour.....	\$44c

In many cases the attendance to electrical apparatus put at 30 cents per hour, may easily be left out. In this system, when the light reaches the places to be lighted, it has lost about 40% of its intensity; but in order to keep on the safe side, let it be supposed that not more than 50% is available. This expenditure will give a light equivalent to 17,500 candles, or 1,166 gas burners of 15 candles each. This number of burners will consume 5,880 cubic feet of gas per hour, which will amount to the light given by about 400 pounds of adamantine miner's candles. The amount of candles at 15 cents per pound is equal to \$60 per hour, against 84¢ cents per hour by the electric light.

Let it be noticed that a No. 7 Brush machine gives a light equivalent to 35,000 candles when it feeds 10 or more lamps; but if it was made to

feed a single lamp, the result would be greater, which, nevertheless, has not been accounted for in the above estimate.

Let it also be noticed that in the above estimate it has not been taken advantage of the vacuum properties of the voltaic arc, above mentioned, nor of the advantages to be derived from the use of the quinine sulphate, which, nevertheless, both are well ascertained. In the above example all the items and expenses are perfectly warranted by actual practice; and if any deviation of the written figures has to be

Fig. 4.

DISBURSING LENSES WITH AND WITHOUT REFLECTOR.

taken, it will be greatly in favor of the electric arc.

PLANTS IRRIGATING FOR THEMSELVES.—It has been shown by the experiments of the late Prof. Habblerlandt, that plants sometimes irrigate on their own account and thus draw nutrient from dry soils. He undertook a series of experiments on the phenomena of vegetation of plants grown in an absolutely dry soil. For this purpose he allowed the lower portion of the roots of the plants experimented on to dip down into distilled water, while the upper portion

The Mexican International Exhibition.

Some time ago the cables brought the report that the Mexican exposition had been abandoned, and we made a note of this fact, but now it appears that the report was a mistake, and that it was only postponed. It was known that some of the most active friends of the project thought the time too short for preparation, and were in favor of extending the date of open-

Fig. 5.

ing for a year. This seems to be the state of the case. Mr. Yharrola, who has been acting for the Mexican government in the matter, is now in this country to arrange for extending the time of the completion of the building, and the exposition will open January 1st, 1880. We would be glad to give positive assurances that such is the case, our only authority, and it is undoubtedly good, is the *Iron Age*.

Our commercial relations with Mexico might be considerably improved, the continuity of the nations afford natural facilities for all business purposes, and Mexico certainly desires amic-

FIG. 3. SECTION OF LAMP AND CHAMBER OF LIGHT.

was retained in a soil so dry that the plants would otherwise, as was practically demonstrated, inevitably be withered up. The results of these trials went to show that the portion of the roots lying in the upper dry stratum of soil rich in nutritive constituents of plant life does not remain inactive, as has been generally maintained, but is chiefly occupied in supplying the plant with the constituents of its ash. As there is no absolute want of water, this being supplied by the lower portion of the root, the upper portion is enabled to secrete a certain quantity of moisture which is taken up by the im-

mediate relations with the United States. Yet, singularly enough, we regard her somewhat in the light of a child to be corrected, while European nations, particularly England, regarding her as a full-grown nation, although revolutions occur as frequently almost as the diurnal revolution of the earth on its axis, and draws from Mexico millions of dollars annually on account of trade. Some day, unless we have more respect for the Mexican pesos, England will have a bullion in supply exceeding our own, and this with an established trade will enable that government to recover her diminished com-

Fig. 6.

Fig. 7.

SYSTEM APPLIED TO DESK LAMPS.

mediately surrounding oil, and dissolves its earthy constituents, which are then taken up directly by simple endosmosis.

SECRETARY EVARTS has authorized the postponement of the report from the Paris exhibition until September 1st, as 16 of the 24 reports have not yet been made. The Secretary will not wait for those that are not ready by that time. The more important reports yet to be received are W. W. Story's on art, Ferguson's on fishes, Donald G. Mitchell's on household goods, Sweeney's on machinery, and Blake's on ceramics. The reports will make several volumes altogether.

Prospects of California Mining.

We agree with the New York *Bullion* that "the English have been large purchasers of our mining properties in almost every prominent field, but nowhere have they been so successful with their patient, thorough methods, as in the gold gravel and quartz mines of California. Extraordinary richness of ores demoralize English system as quickly as they do American system, but the large and apparently interminable bodies of low-grade ore, and the cubic miles of gravel, with a few grains of gold to the yard, in California, fit the Englishman, and as a result we constantly hear of new and extensive purchases by them. These cases are very similar. Mines worked for years on the usual hand-to-mouth waiting-for-a-big-strike style, sold at last for a tithe of what is in sight, developed adequately a few months and increased in market value a thousand per cent. We are firmly of the opinion that California's capacity of gold production is as great to-day as in 1850. In both gravel and quartz deposits she is unequalled, and she has but fairly prospected both. In 30 years California yielded more than a thousand million dollars, mended more broken fortunes, and created more than any similar territory ever did in like period. Put one-twentieth of her yield into her quartz and gravel mines now, in the light of her experience, and California will be a gold mint for the world for the next century. Nowhere in the world is there so great assurance of regular and permanent production in gold mines. We look with keen interest on the systematic development of California's mines, believing that they will sustain the State's title of The Golden, against all comers, and we regard the State as the most important gold producer on the globe."

It is of every day experience that one man will realize an income from another man's waste, and the feverish search for rich ore, nuggets and outcrops hurriedly picked over have caused more modest riches to be despised. Our State has not been fully tested as to its mineral producing capacity, and many localities exist which have only been superficially examined, a closer exploration of which will undoubtedly create astonishment at the extent of the precious metals waiting to be worked up.

California is not a close corporation, her capitalists do not hesitate to make outside investments, and are certainly entitled to a justifiable pride in the fact that our resources are drawing the attention of shrewd capitalists from other quarters. The time for petty sectional jealousy has passed, and we have become practically cosmopolitan. If anybody finds fault with our mining system, we are ever ready to receive suggestions of improvement in good spirit. As pioneers, however, our miners have a wide influence for the weal or woe of the mining interests of our Golden State; for its weal by a fair exposition of our capacities; for its woe, by a delusive or false estimate of local values. We cannot claim a monopoly, because the precious metals are found elsewhere than in our State, and the necessity existing for supplying the world's bullion, now greatly deficient, forces the development of mines and the more careful and economical extraction of the precious metals, and in inviting capital to this State we do so with the conviction that our numerous but attainable deposits, if not quite so rich as the reported fabulously rich strikes in some other States and Territories, do not cost two dollars for every dollar extracted, nor endanger the life of the miner by reason of the unsettled condition of society and mixed ideas of law and order.

SALMON DISEASE.—The salmon disease afflicting the fish of Scotland is causing considerable anxiety, and it is feared that it will extend to all the rivers of the country. Sir Robert Christison, Bart., describes the disease as "a branching fungus which attaches itself in the first instance to those parts of the fish which are destitute of scales." The irritation thus produced causes the fish to rub its scales off against the sand and gravel, in doing which great cuts and gashes are inflicted, leading to death by exhaustion. Carefully conducted inquiry has failed to reveal the cause of this epidemic, which last year killed multitudes of salmon and seems no less destructive this year. There is no longer any disposition to attribute it to town sewage, as experts agree that the influence of all the refuse that goes into the rivers is inadequate to account for it.

A HAPPY EVENT.—We learn with pleasure that Thomas J. Davis, for several years foreman of the *PRESS* printing establishment, has concluded to change for the better, his condition in life, with the consent and connivance of Miss Grace Bartling, with whom Mr. Davis was united on the 16th instant. The columns of this paper have been indebted to Mr. Davis for their attractive appearance, and we hope his married life will be as pleasant as his efforts in that direction have been successful. We have nothing but our most earnest congratulations to offer the new couple upon their favorable venture upon the sea of matrimony.

The exports of British Columbia for the quarter ending June 30th reached \$145,155.

NOTICE TO THE MINING PUBLIC.

MESSRS. RANKIN, BRAYTON & CO., of the Pacific Iron Works, are the only parties authorized to manufacture HOWELL'S IMPROVED WHITE FURNACE under the License of this Company.

THE STETEFELDT FURNACE CO.,
By C. A. STETEFELDT, President.

Referring to the above, the undersigned would call attention to the fact that by a compromise recently effected with the STETEFELDT FURNACE COMPANY, they have secured the use of all the patents of said Company applying to

Revolving Cylinder Furnaces,

And are thus enabled to give purchasers the license of all patent claimants, to-wit:

WHITE, HOWELL, THOMPSON,

— AND THE —

Stetefeldt Furnace Company,

Thereby avoiding all further litigation in reference to these rival claims. The great

SUPERIORITY OF THE FURNACES

Embracing these patents has been satisfactorily demonstrated. There are now some thirty of them in operation in the various mining districts of the coast, operating in all cases with economy and satisfaction, working in many localities

THE BASEST AND MOST REFRACTORY ORES UP
TO 90 AND 95 PER CENT.

By an improvement—the patent for which has recently been allowed—this Furnace can be readily adjusted so as to work with equal facility and effectiveness all classes of ores.

The following are some of the Mining Companies who have recently adopted this Furnace, the most of which are now in successful operation, many of them running two and some three and four Furnaces.

NEVADA.—Grand Prize, Star, Martin White, High-bridge, Columbia, Alexander, Paradise Valley, Jefferson, Leopard, Eagle, Endowment, Independence.

ARIZONA.—Tiptop, Tiger, Peck, Hackberry, Corbin, Tombstone, Bradshaw.

OREGON.—Monumental.

MONTANA.—Alice Mine, Butte City.

MEXICO.—Trinidad, Harnaguera, Momoscs.

PERU.—Cerro de Dasco.

RANKIN, BRAYTON & CO.,
Pacific Iron Works.

CAUTION.—All persons are hereby cautioned against buying from other parties Furnaces embracing the improvements covered by the patents above mentioned, as they will be vigorously prosecuted and involved in heavy damages.

WASHING! WASHING!

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

FOR SALE. COMPLETE THRESHING OUTFITS,

Consisting of HOADLEY'S STRAW-BURNING ENGINE, 15 horse power, JACKSON'S REMODELED PITT THRESHER, with Feeder, Elevator, Derrick, Forks and Water Wagon,

\$2,500 to \$3,000,

Fully Guaranteed to Equal the Best Improved Outfits in the Market.

Also, one four-sided, six-inch SMITH'S MOLDING MACHINE, and one HOADLEY WOOD-BURNER 12 horse power, at a bargain. Also, new 3½-inch Thimble-Skein Wagons at \$75, and 10-foot WINDMILLS at \$80.

Machine Work and Castings of all Kinds to Order.

— FOR CIRCULARS ADDRESS —

Jackson Agricultural Works,

S. E. Corner of Sixth and Bluxome Streets, near S. P. R. R. Depot, San Francisco.

SAVE YOUR GOLD! Highly Important to Miners and Quartz Mill Men! SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, - - - PROPRIETOR.

THE ELKINS "BOSS" GOLD AMALGAMATOR.

Is the Best, Simplest and Cheapest
Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 100 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a ½-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 381 Pine Street, - - SAN FRANCISCO.

Pioneer Plating Works.

MANUFACTORY OF

Silver Plated Amalgamating Plates,

For Quartz Mills and Gravel Claims. Are prepared to furnish any size Plate promptly and satisfaction guaranteed. Old Copper Plates purchased, Plated or the Gold Extracted by the most complete process, at small cost, and the copper saved.

The best Work done on the most reasonable terms on the Coast.

Barlow J. Smith, M. D.

Consulting Physician,

Professor of Phrenology and
Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny.

This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electrized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervous derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motopathy the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermal, Russo-Turkish and Medicated Baths given daily. Mrs. Dr. Smith as Matron has charge of the female bathing department.

Dr. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiology, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE of Phrenology that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness; whether CONSUMPTIVE, DYSPEPTIC, RHEUMATIC, APOPLECTIC, NEURALGIC, LEUCORRHEAL, or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds. Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examinations with Fowler and Wells' harts, will meet with a respectful reception at his consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph.

Phrenological or Physiognomical examinations without charts, \$1.50; with charts from \$3 to \$5.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 5 P. M. Sundays from 9 A. M. to 12 M.

Orders for Mining and Scientific Books in general
will be supplied through this office at published rates.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Ad-
justed than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoist-
ing coal or building material, etc. It will do the work of a
Steam Engine with one-tenth the expense. One Horse ca-
sily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be
affected by exposure. The hoisting-drum is thrown out of
gear by the lever, while the load is held in place with a brake
by the man tending bucket. The frame of the Power is
built to hold timbers, thus avoiding all frame work. When
required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked
wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp,
Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Rifles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

SANDERSON BROS. & CO.'S

Best Refined Cast-Steel.

Warranted Most Superior for Drills, Hammers, Etc.

A full and complete stock of this reliable and well-known
brand of Steel, for mining and other uses, now in stock and for sale

At No. 417 Market St., S. F., - H. D. Morris, Agent.

BUTTS'

IMPROVED ANTISEPTIC "CHALLENGE"

Fruit, Vegetable and Hop Drier AND CANNING APPARATUS.

The cheapest, quickest and greatest labor-saving Drier ever
introduced. Retains the quality, color and flavor of the fruit.
The Canning Apparatus has a capacity of from 500 to 4,000
cans per day. Machines varying from 500 lbs. to 10 tons cap-
acity per day constantly on hand. For Circulars, prices, etc.,
address

WM. BUTTS, Patentee,

S. E. Cor. Spear and Miselón Sts., San Francisco.
P. O. BOX 1,859.

22 State, County and Individual Rights for Sale.

C. C. Bitner's Apparatus for Obtaining Met- allic Copper from its Solutions.

Patented March 18th, 1873. Will precipitate with steam in
three hours, requiring no machinery to run it. Cost of con-
structing apparatus, \$75. The old cylinder process takes
four hours to precipitate and costs from \$1,200 to \$1,500 to
construct, besides the machinery to run it. For right to use
my Precipitator address C. C. BITNER, Spenceville, Ne-
vada County, California.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Me-
chanical Movements, illustrated and described. Inventors,
model makers and amateur mechanics and students, will
find the work valuable far beyond its cost. Sold by
DEWEY & Co., Patent Agents and publishers of Mining
AND SCIENTIFIC PRESS, San Francisco. Price, \$1, (post paid)

Machinery.

GOLD AND SILVER Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgama-
ting Pans and Separators for Gold and Silver Ores, Chloro-
dizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel
Shoes and Dies for Stamps, and every description of Mine
and Mill Supplies.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is
made complete with wrought-iron frame ready to put upon
the foundation, requiring no skilled millwright. These mills
are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold
Mill, including Crucible, Steel Shoes and Dies, Boiler and
Engine, Counter Shafing, Pulleys, etc., Stamps weighing
450 lbs. each, with Copper Plate inside of the Mortars, and
for tables outside, making all the Machinery complete for a
10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900
lbs. for gold or Silver Ores. Wet or dry Crushing Mortars.
Will contract to erect complete Gold and Silver Mills on the
most improved plans. We have 30 years' experience in min-
ing and milling Gold and Silver Ores, and can compete with
the world. Send for a circular. Address

terests.

The Hayford Process.

We lately published an item headed "Preserving Timber by the Hayford Process a Failure," reprinted from the *American Ship*. We supposed the authority to be reliable, and as we do not wish to injure the development of any improvement in wood-preserving processes, we willingly give space to Edward R. Andrews, the proprietor of the Hayford system of wood preservation, No. 4 Postoffice square, Boston, who has written us a personal letter upon the subject. Mr. A. says the article in the *American Ship* is entirely false, and originated in his refusal to give that paper an advertisement. If this be true, it is sufficient to condemn any journal guilty of this petty revenge.

Samuel H. Pook, Naval Constructor of the U. S. N., in his official report on the timber creosoted by the "Hayford" process in the steamship *Vandalia*, after six years service found the timbers still impregnated with creosote, and as Mr. Andrews justly says: "If the strength of the timbers of this *Vandalia* had been destroyed by the creosoting process the *Vandalia* would not have been pronounced sound and permitted to go to sea again without repairs."

The whole amount of timber creosoted in the *Vandalia* was 650,029 feet, hoard measures, being white oak timber and plank and 400 knees, as well as white and yellow pine timber and plank.

Dr. Von Baumhauer, Commissioner of Centennial exhibition from Holland, approves of the Hayford process, gives numerous instances in his report upon the teredo navalis of the success of this creosoting process in preserving timbers exposed to the ravages of that marine horer.

John Bogart, of the American Society of Civil Engineers, in his pamphlet upon the use of timber preserved and unpreserved, cites also numerous instances of the value of the Hayford process and its practical success as demonstrated by its proprietor.

Our space is limited and we cannot do full justice to this important subject. From all accounts we feel at liberty to say that the *American Ship* is in error as to the practical results of the creosoting process.

A Correction.

EDITORS PRESS:—In the article entitled "Intersecting Cable Wires," which appeared in your issue of July 12th, there are one or two errors which you will please do me the kindness to correct. Referring to my new penetrable grip, it is stated in that article that "the flange is broken only to admit the intersecting cable passing through at right angles, the passing cable turning the notched wheel and directing the cable into the next wheel and so on until passed. The lower gear of the grip—that part below the notched wheels—is provided with an inclined plane projecting out in front of it, which forces the cross cable upon a pulley attached to a stationary cable lifter, and thence on and in between the notched wheels." * * * Now the notches in the wheels are sufficiently large to receive not only the intersecting cable but also a bar which is attached to the cable lifter and which alone turns the wheels. The inclined plane mentioned above does not come in contact with the intersecting cable, but it simply raises the cable lifter. The intersecting cable rests on a pulley attached to the cable lifter in the same manner as it rests on other pulleys placed at intervals throughout its length, and this pulley is the only thing at the crossing that touches the intersecting cable when it is being crossed. The cable is merely gently raised up by the pulley on which it runs and it then passes entirely through the grip absolutely without touching any part of it, after which it is lowered to its former position.

VITRUVIUS FRAZEE.

San Francisco, July 12th.

A SWISS EXHIBITION.—Switzerland has appointed the year 1881 for an international exhibition of watches, jewelry, snuff boxes and musical boxes—a display in which the ancient republic may well call the rest of the world to see what she can do. This project adds another illustration to the recent tendency of international exhibitions, especially in smaller countries, to run to specialties. This will be the first exhibition of the sort in Switzerland.

THE NEW JERSEY SUPREME COURT has affirmed the death sentence pronounced against Mrs. Smith and Cove Bennett for the murder of the former's husband at Jersey City. What became of the money raised to procure a reversal?

THE CENTRAL PACIFIC RAILROAD uses a hand car with three wheels for one person. Weight of car 100 pounds, propelled by hand or foot. Speed about 18 miles per hour.

A "PACIFIC LADIES' ESCORT COMPANY" is about to be organized in San Francisco with branch agencies all over the coast. A prospectus will soon be issued.

PORTABLE GAS is sold and delivered in England like milk. People in the country and villages receive it in copper vessels from large cities.

	1852-1875			7,234,392	7.8
Total		12,828,270	100.0	93,519,908	100.0

The Production of Gold and Silver.

Inasmuch as money made of gold and silver forms the basis of all commerce, the production of these commodities cannot fail to interest all concerned in trade, even in the remotest way. In fact, we may go farther and say that it has an importance for each and every individual among all nations and all peoples, and in all time. Especially must it interest the people of the Pacific Coast. Everything bearing on it should particularly interest the readers of a commercial paper. Now, there are hundreds of experts all over the world who make a business of studying the relations of gold and silver to each other, the methods of the production, and the influence of that production on trade, commerce and the progress of peoples and nations. One of these is Dr. Adolf Soetbeer, whose nationality may be surmised from his name. He has examined most of the facts connected with the production of the precious metals from the period of the discovery of America by Columbus, and come to conclusions from his repository of information appear in the London *Economist* of a recent date.

These are in the highest degree interesting. We have converted the kilograms, in which the weight is expressed in the original tables, into pounds avoirdupois, as being most familiar to our readers. It would appear from the first table that Mexico has produced 25 per cent. more than one-third of all the silver; Peru and Bolivia more than one-sixth each, and that these three countries of South and Central America have together produced more than four-fifths of all the silver that has been given to the world during the past four hundred years. The United States is low down in the scale, producing only one thirty-sixth of the whole, while, contrary to the received opinion, Germany and Austria-Hungary exceed each the United States by more than 50 per cent.

In the gold product the United States bears the palm, having produced somewhat less than one-fourth of the whole; Australia about one-tenth less than the United States; the Russian Empire and Brazil, respectively, about one-half the proportion of the United States; New Granada a little more than one-half; Austria-Hungary comes in for about one-half the proportion of the Russian Empire.

Table No. 1. shows that the proportion of gold, owing to the quantities brought from America by the first Spanish conqueror, was then much greater than at any subsequent period for three hundred and fifty years. It decreased proportionately with silver for more than one hundred and fifty years, increased slowly till 1841—then rapidly till 1860, on account of the discoveries in California and Australia, when it made up one-fifth of the whole weight of gold extracted. Since then it has decreased to less than half the amount. One-ninth of all the gold was extracted in five years, between 1856 and 1860.

Table No. 2. gives the coinages in pounds avoirdupois for twenty-four years, and shows

that that of France was in gold one-third of the whole; the United States, about one-half that of France, Great Britain following a little behind the United States. In silver coinage British India took the palm—only one-fifth less than one-half of the whole value, in dollars being about \$670,000,000 out of a total of \$1,500,000,000. France came in next with one-fourth the proportion of British India; Germany a little lighter than France; Austria-Hungary with three-fourths that of France; the United States about 41 per cent of that of France; Great Britain about one-half of that of the United States.

There is one feature of these tables that deserves note, and that is the apparent discrepancy between the amount of gold and silver produced and coined—the latter being largely in excess. The discrepancy is all the greater when it is reflected that a good deal of the precious metals produced has been used in manufactures and arts. The quantities produced and coined compare as follows:

	Gold—lbs.	Silver—lbs.
Coined	12,828,275	93,519,908
Produced	10,453,973	68,208,415

Excess coined..... 2,343,303 25,311,493

This shows that there has been a great deal of re-coinage, for that is the way in which the apparent excess comes.

STATEMENT OF THE TOTAL PRODUCTION OF PRECIOUS METALS FROM 1493-1875.

Countries.	According to Weight—Silver, Lbs.	Gold, Lbs.
Germany	17,390,862	
Austria-Hungary	17,094,297	
Various European Countries	15,240,400	
Russia	5,348,558	
Africa	1,609,320	
Mexico	187,551,800	
New Granada		2,671,900
Peru		359,810
Potosi (Bolivia)		545,810
Chili		679,910
United States		2,281,510
Australia		4,457,420
Various Countries		336,440
Total	397,725,187	20,797,359
Value of silver (estimated)	\$5,400,000,000	
Value of gold (estimated)		\$2,000,000,000
Total		\$7,400,000,000

Of the total value of silver, Mexico, Bolivia and Peru have produced \$4,150,000,000; Mexico herself more than one-half; the United States over \$185,000,000; Europe over \$906,000,000. Of the total value of gold, the United States is credited with nearly \$1,300,000,000; Australia with over \$1,100,000,000; Russia with about \$290,000,000; South America with the greater part of the balance. These figures only come down to the close of 1874.

THE WEIGHT OF GOLD AND SILVER COINED BETWEEN 1851 AND 1875, ACCORDING TO PERIODS.

Period.	Gold.	Proportion of Percent age.	Silver.	Proportion of Percent age.
1851-1855	2,525,534	19.8	10,942,514	11.8
1856-1860	2,802,976	22.0	11,579,316	12.3
1861-1865	2,455,48	19.3	10,534,492	11.2
1866-1870	2,010,338	15.9	9,326,450	10.0
1871-1875	2,922,942	23.0	10,233,576	11.0
Total 1851-1875		100.0		100.0

ESTIMATE OF PRODUCTION OF GOLD FROM 1875 TO 1878.

	1876.	1877.	1878.
United States	\$47,000,000	\$45,000,000	\$39,000,000
Australia	47,500,000	35,000,000	35,000,000
Other Countries	30,000,000	30,000,000	30,000,000
Total	\$114,500,000	\$110,000,000	\$104,000,000

Proportion of gold to production of precious metals..... 8 1/2 p. c. 7 1/2 p. c. 8 p. c.

PRODUCTION OF SILVER.

	1875.	1877.	1878.
United States	\$40,000,000	\$45,000,000	\$36,000,000
Mexico and S. Am. C.	27,500,000	30,000,000	27,500,000
Other Countries	10,900,000	10,000,000	10,000,000
Total	\$78,500,000	\$85,000,000	\$73,500,000

Proportion of silver production..... 91 1/2 p. c. 92 1/2 p. c. 92 p. c.

Total gold & silver \$192,000,000 \$197,000,000 \$187,500,000

NOTE.—The above tables are in pounds avoirdupois, and are given so, as the public are more familiar with them. One hundred pounds avoirdupois is equal to 121 1/2 pounds troy—nearly one-fifth added to these above figures, therefore, gives nearly the pounds troy.

The total amount of gold and silver coin in the world does not exceed \$5,500,000,000—\$3,000,000,000 for gold and \$2,500,000,000 for silver, and the total amount used in the arts, etc., does not exceed \$10,000,000,000, so that there is here a real or apparent loss of \$4,500,000,000 or nearly thirty per cent. in less than four hundred years. And this takes no account of the large amount of gold and silver in existence at the time of the discovery of America by Columbus. It is pertinent, therefore, to ask what has become of all this. —S. F. Journal of Commerce.

News in Brief.

THE corn crop in Iowa is said to be the best in years.

THERE is not a single Russian soldier left in Roumania.

HALF a dozen sunstrokes occurred in St. Louis last Saturday.

BULLION in the Bank of England decreased £38,000 the past week.

AN earthquake agitated the people of Victoria, B. C., July 12th.

THE Bank of Bengal has reduced its rate of discount from 6% to 5%.

THE funeral of the Prince Imperial was an imposing demonstration.

PART of the striking colliers at Shemokin, Pa., resumed work yesterday.

A SEVERE earthquake was experienced at Alexandria, Egypt, July 11th.

SPECIE in the Imperial Bank of Germany last week decreased 7,860,000 marks.

FOURTEEN fires occurred in San Francisco from July 3d to the 6th, inclusive.

DURING the past week specie in the Bank of France decreased 30,000,000 francs.

GEN. VON MANTEUFFEL is to become Governor of Alsace-Lorraine in August.

A PARTY of 650 Mormons, en route to Salt Lake, have arrived at Council Bluffs.

THE German Reichstag has finally passed the protective customs tariff—217 to 117.

THERE is 25 feet of snow in Emigrant Gap, near the summit of the Sierra Nevada.

QUITE a considerable emigration is taking place from New England to Tennessee.

THE recent heavy rains in British Columbia have had a disastrous effect on the crops.

THE Orange procession at Toronto last Saturday was the largest seen there for many years.

CHINESE-AMERICAN war wages in the shoe shops at North Adams, Mass. Chinamen whip.

PRINCE JEROME BONAPARTE has virtually assumed the attitude of chief of the Imperialists.

GEN. SIR GARNET WOOLSEY arrived at Cape Town July 15th, and immediately left for Natal.

Lathe Without Saw Attachments.

This lathe has been made especially to meet a want felt by many for a really good and substantially made Foot-Lathe at a reasonable price, and we think that we can safely say that it is far the best lathe ever placed on the market at the price asked. The bed, head, and tail stocks are of iron, the spindles of steel. The bearing of the head stock is central, so that the wear can be easily taken up.

Material eighteen inches long and eight inches in diameter can be turned upon it. The pieces that accompany this lathe without extra charge are two T rests, two plan centers, one spur center for wood turning, and one face plate.

Price of Lathe without Saw Attachments.....\$15. Price of Lathe with Scroll Saw Attachment.....\$55.
 Price of Lathe with both Scroll and Circular Saws, \$70.

Trump Drill Chuck.

Chuck for drills 1/2 and under, Price.....\$1.60
 Chuck, for drills 1/2 and under, Price.....\$2.25
 They are made on solid steel plug, centered and readily fitted to Lathe or Drill Press.

Works, Chester, Pennsylvania. 407 Library St., Philadelphia

Union Brass Foundry and Mechanical Work Shop.

GIOVANNINI & CO.,

417 and 419 Mission Street, - - SAN FRANCISCO.

The attention of our customers and especially of those interested in Water Works, Gas Works or Mines is respectfully called to our very important improvement in the construction of Stop Valves (or Gates). They differ from all others in that the inner faces are perfectly parallel, therefore when the Gate or Valve is to be opened, at the first movement of the screw the center block (see cut) releases the disks from their bearings, so that they will move easily and prevent the wearing of the inner faces. This Gate has proved very efficient in Pipes of all sizes, and under any pressure and from its double form and perfect joint formation is especially valuable for use in large Pipes for water, steam and gas, and from its avoidance of any wedge shape cannot jam at any point (see cut).

The G. & B. Valves (or Gates) have no equal in simplicity of construction of all working parts, ease of access for repairs, and durability. We have recently enlarged and fitted up our Brass Foundry and Shop with all the latest improved Tools and Machinery, thus greatly increasing our facilities for rapidly executing orders for all sizes of Stop Valves (or Gates) from three-inch to four feet in diameter, or any size, to order. We guarantee them to give better satisfaction, cost less money, and last longer than any other Valve in use.

We are also prepared to execute all orders in Brass Work for Breweries, Distilleries, Plumbers, Gas and Mining Apparatus, Ship Work, Soda Apparatus, Steam Fittings, Meters, Gauges and Indicators. Also in Machine Pattern and Model Making, and Clock Work. Gear cut to order. Brass Castings of all kinds. We are confident of our ability, and all orders entrusted to us will be executed with promptness and dispatch.

BUY LAND

Where you can get a crop every year;
where you will make something every
season; where you are sure of having a crop
when prices are high; where you have a
healthy place to live; where you can raise
semi-tropical as well as other fruits; where
you can raise a diversity of grain and vege-
tables and get a good price for them. Go
and see the old Reading Grant (in the
upper Sacramento Valley), and you will
find such land for sale in sub-divisions to
suit purchasers—at reasonable rates and
on easy terms. Send stamp for map and
circular to EDWARD FRISBIE, proprietor,
(on the Grant), Anderson, Shasta Co., Cal.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT
for DIAMOND POINTED DRILLS, now brought to the
highest state of perfection, are prepared to fill orders
for the IMPROVED PROSPECTING and TUNNELING
DRILLS, with or without power, at short notice, and
at reduced prices. Abundant testimony furnished of
the great economy and successful working of numerous
machines in operation in the quartz and gravel mines
on this coast. Circulars forwarded, and full infor-
mation given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

Improved Grounds For Sale

NEAR SAN JOSE.

The subscriber offers for sale a tract of land, 40 acres in ex-
tent, located half a mile south of the road from San Jose to
Alum Rock, and four miles from San Jose—directly in the
warm belt of the foothills. The grounds are pleasantly and
conveniently located, and under a high state of cultivation.

Five Acres in Orchard,

—CONSISTING OF—

Orange, Lemon and Lime Trees, Nuts,
FIGS, BANANAS,

Together with a great variety of other Fruits, large and
small, and GRAPES. The Banana ripens readily in this
locality. TWO ACRES are set off for an

ORNAMENTAL GARDEN,

Which is now filled with Shrubs, Flowers, and a fine growth
of ORNAMENTAL TREES, 170 in number, now 10 years
old. In connection with these grounds there is now a

Small Cottage and Farm House,

Well built and hard finished. On the higher ground there is a
FISH POND,

40 by 80 feet in extent, and 3 feet deep, well stocked with
Carp and Trout. The pond is supplied with water from a
never-failing spring a few feet distant, which delivers 24,000
gallons of water every 24 hours the year round. The pond is
at an elevation of 20 feet above the house, and from it pipes
are laid for irrigating the orchard and garden, and supplying
the house.

This balance of the place is now devoted to grass and grain,
but may be improved for orcharding or other cultivation if
desired.
This place affords a rare opportunity for anyone desirous
of securing a well-improved locality for an elegant country
residence, and will be sold at a great bargain. For further
information apply either at this office or of the proprietor on
the premises.

Mineral Veins.—No. 1.

The importance of a correct theory concerning mineral veins cannot be overestimated, particularly on this coast where prospecting for the precious metals is so common. The absence of proper knowledge has disappointed the hopes of many, who, deceived by small pocket finds or partial strikes, waste their means in the attempt to develop an illusion. In the hope of satisfying many inquiries concerning this apparently controverted subject of mineral veins, we find in Le Conte's "Geology," published by D. Appleton & Co., N. Y., a clear illustration of the system:

All rocks, but especially metamorphic rocks in mountain regions, are seamed and scarred in every direction, as if broken and again mended, as if wounded and again healed. All such seams and scars, of whatever nature and by whatever process formed, are often called by the general name of *veins*. It is better, however, that dikes and so-called granite veins, or all cases of fissures filled at the moment of formation by igneous injection, should be separated from the category of veins. True veins, then, are accumulations, mostly in fissures, of certain mineral matters usually in a purer and more sparry form than they exist in the rocks. The accumulation has in all cases taken place slowly.

Thus limited, veins are of three kinds. *Veins of segregation*, *veins of infiltration* and *great fissure veins*. These three, however, graduate into each other in such wise that it is often difficult to determine to which we must refer any particular case. Some writers make many other kinds.

In veins of segregation the vein matter does not differ greatly from the inclosing rock. Such are the irregular lines of granite in granite, the lines differing from the inclosing rock only in color or texture; also irregular veins of feldspar in granite or in gneiss. Under the same head belong also the irregular streaks, clouded and blotches, so common in marble. In these cases there seems to be no distinct line of separation between the vein and the inclosing rock—no distinct wall to the vein. The reason is, these veins are not formed by the filling of a previously existing fissure, but by the segregation of certain materials, in certain spots and along certain lines, from the general mass of the rock, either when the latter was in plastic condition from heat and water, or else by means of percolating water, somewhat as concretions of lime, clay, iron ore and flint, are formed in the strata.

Veins of infiltration originate in metamorphic rocks which have probably been subjected to powerful horizontal pressure. Besides the wide folds into which such rocks are thus thrown and the great fissures thus produced, the strata are often broken into small pieces by means of the squeezing and crushing. The small fissures thus produced are often filled by lateral secretion from the walls, or else by slowly percolating waters holding in solution the more soluble matters contained in the rocks. The process is similar to the filling of cavities left by imbedded organisms, and still more to the filling of air blebs in traps and lavas, and the formation of agates and carnelian amygdulæ. In veins of this kind, therefore, a beautiful *ribbon structure* is often produced by the successive deposition of different colored materials on the walls of the fissure. Veins of this kind also, since they are the filling of a previously existing fissure, have *distinct walls*. The filling consists most commonly of silica or of carbonate of lime.

Fissure veins are fillings of the great fissures produced by movements of the earth's crust. When these fissures are filled at the time of formation by igneous injection they are called *dikes*; but if subsequently with mineral matter, by a different process, to be discussed hereafter, they are *fissure veins*. These veins, therefore, like dikes, outcrop over the surface of the country often for many miles, 50 or more. Like dikes also they are often many yards in width, and extend to unknown but certainly very great depths. Like dikes and fissures also they occur in parallel systems.

The most obvious characteristics of the veins

of this class are their size, their continuity for great distances and to great depths, and their occurrence in parallel systems. As the vein is a filling of a previously existing fissure, this distinction between the vein and the wall-rock is usually quite marked. In many cases, in fact, the vein-filling is separated from the wall-rock by a layer of earthy or clayey matter called a *selvage*, as if the sides of the open fissure had become foul by percolating waters carrying clay, before the fissure was filled with mineral matter. The contents of fissure veins are also far more varied than those of other classes.

Although more regular than other kinds, yet fissure veins are also often quite irregular—sometimes branching, sometimes narrowing or pinching out in some parts and widening in others (Fig. 1), sometimes dividing and again coming together, and thus inclosing a portion of the wall-rock (Fig. 2). Such an inclosed mass of country rock in the midst of a vein is called a "*horse*." Many of these irregularities

mentioned above may contain metals, but the segregative veins are usually too irregular and uncertain, and the infiltrative veins too small, to be profitable. True, profitable metalliferous veins are almost always great fissure veins.

The contents of metalliferous veins are of two general kinds, viz., *vein-stuffs* and *ores*. The principal vein-stuffs are quartz, carbonates of lime (calc-spar), carbonates of baryta, carbonate of iron, sulphates of baryta (heavy spar), and fluoride of calcium (fluor-spar). By far the most common of these is quartz, and next is calc-spar. Often, however, the vein-stuff is an aggregate of minerals forming a true rock. Nearly the whole of a vein consists usually of vein-stuff. This ore exists in comparatively small quantities, sometimes forming a central rib or sheet, as is deposited last (Fig. 3); sometimes in irregular isolated masses called bunches or pockets, or in small strings, or grains, irregularly scattered through the vein-stuff and extending often a little way into the wall-rock.

same occurs often in amygdulæ, the last filling being crystalline. Sometimes there is evidence of successive openings and fillings, as in Fig. 6, where *a* represents quartz crystals, interlocking in the center and based on agate layers, *b b*, while *c* represents quartz with disseminated copper pyrites. In this case it seems probable that 1 and 2 were the walls when the agate and quartz filling took place, and that afterward this fissure was reopened along 2, so that the walls became 2 and 3, and the new fissure thus formed was filled with cupriferous quartz. The same is well shown in Fig. 7, where *a, b, c, d, e, f*, are successive quartz combs, separated by 2, 3, 4, 5, 6, which are clay selvages, and therefore old walls.

The relative ages of veins in the same region is determined in the same way as that of dikes, viz., by the manner in which they intersect each other; the intersecting vein being, of course, younger than the intersected vein.

The absolute ages of fissure veins, or the geological period in which the fissure was formed, can only be determined by the stratified rocks through which it breaks. The auriferous veins of California break through the Jurassic; and, as there are good reasons for believing that the Sierras were formed at the end of the Jurassic, it is probable that these fissures were formed at that time, by the foldings of the strata consequent upon the pushing up of this range. The filling, of course, was a slow, subsequent operation, but commenced then.

Mineral veins seldom or never outcrop on the surface in the condition we have described them. On the contrary, there are certain changes which they undergo through the influences of atmospheric agencies, which render their appearance along their outcrop quite different from that of the same vein at some depth below. A knowledge of these changes is, of course, of the greatest practical importance. They are, however, extremely various, differing not only according to the metallic contents, but also according to the nature of the vein-stuffs, and therefore must be learned by observation in each country.

Gold is found either in quartz veins intersecting metamorphic elates (quartz mines) or in gravel drifts in the vicinity of these (placer mines). Originally it existed in the quartz veins usually associated with metallic sulphides, particularly the sulphide of iron (pyrites). If the pyrites be dissolved in nitric acid, the gold is left as minute threads and crystals. Evidently, therefore, it exists in minute threads and crystals scattered through the pyrites. Now, when such a vein is exposed to meteoric agencies, the pyrites are oxidized, partly as soluble sulphate, and carried away, and partly as insoluble reddish peroxide, which remains. The quartz-vein stone is, therefore, left in a honey-comb condition by the removal of the pyrites, and more commonly stained of a rusty color by the peroxide. Among the cells of this rusty, cellular quartz the gold is found in minute, sharp grains, evidently left by the removal of the pyrites. Hence, in an auriferous quartz vein, along the outcrop to a depth of 30 to 60 feet (*i. e.*, as far as meteoric agencies extend), gold is found free in small grains among the cellular quartz; but below the reach of these agencies it is inclosed in the undecomposed pyrites.

If a mountain slope, along which outcrop auriferous quartz veins, be subjected to powerful erosion by water currents, then in the stream beds will be found gravel drifts, composed partly of the country rock and partly of the quartz vein stone. Among the gravel will be found particles of gold, washed out from the upper parts of the veins. By the sorting power of water the heavy gold particles are apt to accumulate mostly near the head of the gravel deposit (bedrock). These gravel deposits are the placers. In these the gold particles, like the stone fragments, are always rounded and worn by attrition.

A MINER at Big Oak Flat, Nevada county, Cal., is prospecting a placer mine by boring a 4½-inch hole. He cuts through any rocks, even the hardest quartz boulders. Fifty feet in nine hours is his average. With the auger used he brings up the gravel and all it contains from any point.

THE bullion shipments from Bodie district from July 1st to 20th amounted to \$147,846.21.

FIG. 7.

THEORY OF MINERAL VEINS, ILLUSTRATED.

are probably the result of movements after the fissure was formed, or even after it was filled. Thus, if *a b c d* (Fig. 1) be one wall of an irregular vein, then it is probable that *a' b' c' d'* was the original position of this wall; but, before it was filled, it slipped up to its present position. Again, movements may reopen a fissure after it is filled. In such cases, if the adhesion of the filling to the wall is strong, portions of the wall-rock are torn away; and if a second filling takes place, a "horse" is formed. Thus *a a a* and *b b b* (Fig. 2) represent the two original walls of an irregular vein; but subsequent movement reopened the fissure to *b' b'* and tore away the horse *H*, after which the vein was again filled.

Veins, of course, usually intersect the strata; but in some cases where strata-planes, or else cleavage-planes, are highly inclined, the opening is between these planes, and the veins are, therefore, conformable with them.

Some metals, particularly iron, occur principally in great beds, being accumulated by a process already described. Others, especially lead, often accumulate in flat cavities between the strata, especially of limestone. But most metals occur in veins. All the kinds of veins

The chemical forms in which metals occur are very various; sometimes they occur as pure metal (as always in the case of gold and platinum, and sometimes in the case of silver and copper), but more commonly in the form of metallic sulphides, metallic oxides and metallic carbonates. Of these the metallic sulphides are by far the most common. It is worthy of remark that all these forms are comparatively very insoluble. The same is true of the vein-stuffs.

The ribboned or handed structure, already spoken of under veins of infiltration, is very commonly found in great fissure veins. This structure is as characteristic of veins as the columnar structure is of dikes. The layers on the two sides usually correspond to each other; sometimes the successive layers are of different color, giving rise to a beautiful, striped appearance. Sometimes the successive layers on both sides are of different materials, as in Fig. 4, in which the central rib, *d*, is galena, and *a a*, *b b*, *c c*, are successive layers of quartz, fluor and baryta. Sometimes, in cases of quartz-filling, the layers are agate, except the center, which is filled up with a comb of interlocking crystals, as in Fig. 5. The

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—E.S.

Developments on Silver Hill, Bodie.

EDITORS PRESS:—The interests of Bodie are being rapidly extended to the southeast of the ground on which are located the Bodie, Standard, etc., properties which have formerly held almost undivided attention. Now we find the ground all about Silver Hill rapidly opening out and exhibiting its rich interior. In addition to the Noonday, Booker, Red Cloud and others which are now contributing largely to the milling interests, we find many smaller shafts, whose future, as indicated by the surrounding developments, bids fair of an equal success. I had occasion to investigate the prospects of one of these opening fortunes through the invitation of Mr. McMurtry, Superintendent of the Glory. This claim, it is supposed, possesses the continuation of the South Noonday ledge, which has already proved itself valuable. The Glory is nearly adjacent to the Booker and lies next to the Noonday proper, thus envied by valuable mines. The shaft is down 30 feet and now holds a ledge twenty inches in thickness. This ledge is formed by the conjunction of two ledges separate on the surface, and the contents consist of the kind of gold-bearing quartz characteristic of the district. The property was recently surveyed, mapped and a company incorporated with the usual capital stock of 100,000 shares. Mr. McMurtry heads operations at present, and the progress is admirable under his supervision. This is one of the many on the same hill, and we may expect shortly to see surprising developments from this hill, as well as farther over in the same direction.

A Glimpse of the Town of Bodie.

To give anything of a reasonable estimate of the population of the growing town of Bodie is rendered impossible by the transient character of its residents; it might now be put at 7,000, and next month, 8,000. As is usually the case with such rapidly growing towns, there is a Main street in the immediate vicinity of which are all the buildings of the town. Imagine a very sterile valley between moderate ranges, with a trend to the north of east; a street running through its lowest part, and, to conform to a partial bend in the valley, changing direction about 10°; bright new wooden houses lining the street closely on both sides, and the property in the rear of these checked over with a few miner's shanties and shops, and we have the town as it now stands. The mountains on the southwest contain the mineral ledges, and are covered with ore dumps and hoisting works which give it a speckled appearance to the distant observer. The miner, in looking at these, points out a pile, and remarks: "There is a brownish dump whose color indicates the presence of gold;" pointing to another dump of a bluish white color, he remarks: "There is evidence either of silver ore or none at all." In these we have the two distinct, noticeable colors of dirt turned out. All of the country within 20 miles is perfectly barren, with the exception of a low sage brush, which fastens itself into the rocks, and seems to ho barely eking out an existence.

The great influx of people arrive by two routes, one from Carson entering at the eastern end of the valley, and the other, on the Pioneer stage line, from Milton by Sonora, entering by the west end. This keeps the town growing in both directions; the eastern end, however, labors under a decided disadvantage inasmuch as the Chinese and disreputable classes have taken up their abode here, and their influence is demoralizing, with a tendency to lower the value of property, and to check the erection of the better class of business houses.

Every variety of business proper seems to flourish; as to the kind of business which predominates, we may say that of every three houses, the first will be a restaurant, the second a saloon, and the third may be occupied by a tinman, a shoemaker, a fruit vender, meat man or barber. The lumber business is an unusually brisk one, and is managed by two firms. The vocation of hooch-lack here fails entirely, the hardy miner needing no polish for his cabin associate or "pard" to admire. Blacksmiths flourish, and the painter soon becomes independent, the houses all being new and waiting to receive the protecting and beautifying coat. Three active papers furnish ample reading matter for the busy population, and nothing could well be added to this branch. One small schoolhouse furnishes all the instruction given to the numerous children, and its tiny bell is the only ring which announces a Christian service, and that seldom more than once per week. This should astonish a Christian people, and the dwellers of Bodie, we hope, will not long remain so utterly destitute of the life-giving truth and instruction.

Investigation shows that the greatest wants are felt in the way of a good foundry and custom stamp mills adequate for crushing the thousands of tons of ore now lying on the dumps of mines whose finances cannot at present furnish funds for the erection of private mills. No investment could be made so profitable as one to furnish custom stamp mills or an

iron foundry. Imagine all the worn-out drills, dies, shoes and milling machinery employed in a mining camp being replaced by metal brought in under a freight of three and one-half cents per pound! The town must have stamp mills and it must have a foundry.

For amusement, there are two halls, termed theaters, where amateurs occasionally perform; but the miner feels no want in this department, as his cabin here is the most acceptable enjoyment for tired limbs and exhausted body. A town crier, hell in hand, with a stentorian voice, proclaims a gathering of the people when there is occasion for an assembly. At evening the street is fairly alive with people passing to and fro—the exclamation is: "Where do they all live!" Nor is there a want of life at midday, the place baving about double the number of laborers required for the mines, and here they loiter around waiting for something to turn up. They ride into the place and frequently walk out, minus what little money they happened to bring.

By strict economy one can live here as cheap as in San Francisco; the contrary of what we should expect of a mining town; but it is a fact, surprising as it may seem. All the luxuries of a San Francisco market may be here enjoyed, everything being freighted from Carson City by large prairie schooners, hauled each by twenty or thirty mules or oxen. These teams may be seen resting in the few side streets, and the oxen lying down present a picturesque appearance, representing "rest from toil." The elderly Piute Indian roams about the town, picking up scraps and rags from the street, while the children and women, with their faces painted and marked hideously, frolic with their dogs or amuse themselves with their rude games. Taking it all in all there cannot be a more stirring people in the State than those whom we find here in Bodie, it being the very essence of life.

JNO. H. WHEELER.

Bodie, July 17th.

Mines and Mining in Tuolumne County.

EDITORS PRESS:—There is greater activity in quartz mining throughout this county at the present time than has been observable for 10 years past, when the business first began to undergo a decline. This decline was due to the usual causes, such as general high prices, extravagance, mismanagement, arising from ignorance and inexperience, to which should be added, as having been here fearfully prevalent, a general lack of thrift and dislike of hard work. Prior to 1869, when only a few of the richer surface ore deposits and pockets, like those on Bald mountain, in Big canyon, at Rawhide ranch, and a few other points on the mother lode, were worked, the results proved satisfactory enough. Afterwards, when deeper exploration became necessary, when these rich pockets were exhausted and lower grade, and sometimes more obstinate ores had to be dealt with, then these pioneer quartz miners, with their big ideas and lack of practical knowledge, soon became discouraged and one after another retired from the field, leaving their claims unworked and the mills standing idle. And thus it was that for the next decade the hullion product and population of Tuolumne gradually decreased and, a slight having come over this branch of mining, all her other industries suffered. And this, not that she had been denied the assistance of capital or really lacked reduction works. Both had been supplied to her liberally. Shafts had been sunk and tunnels run, hoisting works had been erected, and, as we have seen, many mills put up. But it did not avail.

And Wherefore?

How happened it that with all this aid, with all needed appliances and with as good quartz veins as can be found anywhere in California, that this branch of mining has here turned out so badly and been so neglected? The answer is, it was because we had not here the right kind of miners and the right kind of population generally. This section of the State was, as is well known, settled largely by Mexicans and immigrants from Texas and other sections of the Southwest, who naturally drifted in here on their first arrival in the country, many of the more reckless and adventurous having also been originally attracted to this vicinity by the extremely rich character of the surface deposits, for which the mines here were noted. After these deposits had become so far exhausted that hard work, skill and economy were required to make mining pay, these were not the kind of men to render the business a success. These were habits to which these free-and-easy-going people had not been accustomed, virtues that they knew nothing about and which they could not be made to practice. Hence the stagnation and failure, the idle mills, deserted mines, and the general disasters that for so long a time has attended quartz mining here as well also as in some of the counties farther south. It is true we have here even among the pioneer residents some hard-working, frugal men and good miners, but they are in the minority—only as one to two or three of the indolent and thriftless, who, through their preponderance have not only greatly obstructed this branch of mining, but so impressed their characteristics upon the business that it will require yet another decade to work their entire elimination.

A New and Better Element

Has, within the present year, begun to arrive

in old Tuolumne. Trained miners, practiced in the details of the business, capable millmen, metallurgists and assayers have been dropping in upon us, coming sometimes on their own account, and again as the representatives of capitalists—shrewd men conversant with the resources and advantages of the county, and knowing well the obstacles it has had to contend with. Looking about, these miners and assayers have got hold of a number of good properties, buying, in some cases, mines already taken up and partially opened by the incompetents, and in others prospecting for, finding and locating claims, and going to work on them. In adopting the latter course, the skillful assayer has this advantage over the ordinary miner: he is able to know all the while just what the ore he meets with is worth, and also pretty nearly what method will be best adapted for its treatment. For example, this, the old Garrote district, where mining had before greatly languished, has within the past few months been started into new life, simply through the more intelligent methods of prospecting introduced here by men better acquainted with the science of the business, and holding generally more advanced ideas of vein mining than the old crop of prospectors.

The Spring Mine—A New and Important Discovery.

Striking across the country here in an easterly and westerly direction, is to be seen a long and well-defined range of auriferous quartz croppings. These croppings, which can be traced for several miles, appearing at points in great strength, hold their course without variation, indicating the presence of a powerful lode below. Although many claims were located along this range years ago, none of them have ever been much developed. Of late but little attention has been paid to them, this neglect amounting in most cases to an actual abandonment. A few months since there came to this place a young man skilled in metallurgy and assaying, and, in fact, well up in every branch of mining. Observing these neglected but promising mineral indications, he proceeded to examine them more closely, and having obtained a good showing of gold, took up, in connection with two other young men, residents of the place, a company location. Though their means were limited these parties have since developed their claim sufficiently to establish for it a large value. The ore, which is free milling, clean and easily treated, has improved steadily from the surface downward. On ton crushings indicated for it a milling value of not more than \$6 or \$8 per ton, at a depth of 20 feet the grade had advanced to \$12, and since to about \$14 per ton. The drifting and crosscutting, of which a considerable amount has been done, show a body of ore 10 feet wide, reaching as far as excavations have been extended. The lining and other features of the lode, the geology of the formation, and, in short, all the conditions point to the existence here of such heavy, persistent and high-grade ore deposits as will constitute the find a first-class gold mine.

The Effect.

The occurrence of this strike in the Spring mine has stirred up the old prospectors here, and, in fact, tended to animate the entire business of quartz mining in a wonderful manner. The abandoned claims have been re-located and work started on many of the live ones, ore searching having been stimulated also in the country outside. Some of the claims lately opened up on this promising ore range are looking well—notably so the Young Pine, near its easterly end, and from which in years ago a good deal of gold was taken; also the Black Hawk, once somewhat developed but suffered afterwards to fall into a state of decay. Work on the Mount Jefferson mine, situated on a parallel ledge lying quarter of a mile to the north, is also being pushed now with vigor and with every prospect that a valuable ore body will soon be opened up there. This company has a splendid property, and, although this too has suffered from had management in times past, its future is now altogether promising. There are several other mines in this vicinity that present an encouraging outlook and from which a good account may be expected. The Golden Rock company, piping to the east of Big Oak flat, are having a prosperous run this season. They play 1,500 inches in two streams under a 40-foot pressure and wash out about \$200 for each running day.

Groveland, July 12th, 1879.

ARTIFICIAL ULTRAMARINE.—This product has almost wholly supplanted the cobalt dyes, and it has largely taken the place of Prussian and other blues. In 1862 the total production was 3,556 tons; in 1872 it had risen to 8,585 tons, exclusive of the amounts manufactured in an English and in an American factory. The present product is probably over 12,000 tons. The materials employed in the manufacture are soda, sulphur, carbon and silicates of alumina.—*La Gazette Industrielle.*

ARTIFICIAL IMITATION OF NATIVE IRON.—S. Meunier has confirmed his theory in regard to the terrestrial origin of the supposed meteoric native iron of Greenland, by the action of protochloride of iron and chloride of nickel upon fragments of iron in a porcelain tube. He thus obtained a fac-simile, upon a microscopic scale, of the huge blocks which were brought from Disco by M. Nordenskjöld.—*Comptes Rendus.*

Recent Patent Decision.

A case of some importance to the oil stove trade, and of great interest to manufacturers generally as an interpretation of the patent law, has just been decided in the Circuit Court of the United States for the Southern District of New York, by Judge Blatchford. Messrs. C. Riessner & Co., assignees of a patent for improvements in oil stoves, granted to John A. Frey, October 20th, 1874, and reissued June 19th, 1877, brought suit against James L. Sharp for a preliminary injunction. The plaintiffs were represented by Benjamin F. Lee and the defendant by Arthur V. Briesen. Judge Blatchford, in his decision rendered June 7th, denied the motion for an injunction. It seems that Frey assigned to James Henry Thorp the right of obtaining the patent for the Dominion of Canada, which was granted on the 15th of May, 1873, previous to the application for and the granting of a patent on October 20th, 1874, to Frey for the United States. In his reissue of June 19th, 1877, Frey claims as his invention a coal-oil stove called the "Summer Queen," having its wick wheels, wick-wheel shafts and the entire upper surface of its oil reservoir covered by a water reservoir, which protects it, together with a combination of the cap and chimney. The drawing and description of the Canadian patent shows and describes as the first part of the invention what is also described as part of the invention in the United States reissue, which must be regarded as having superseded the original patent.

The United States patent law provides that the American patent expires at the same time as the foreign one taken previous to it, and, as a patent is granted in Canada for five years, it was held that the American patent must expire with it on the 15th of May, 1878. Against this view it was urged by plaintiffs that the extensions granted to the patentee for Canada, for a term of five and ten years, under the provisions of the Canadian law, in March, 1878, would make the American patent run until the Canada patent expires under its extensions; namely, until May 15th, 1888.

The language of the statute, it was said, extended not only to the term of the foreign patent in force when the United States patent was granted, but also the term of any prolongation which the patentee might obtain from the foreign government. The court held, quoting the decision of Judge Clifford in the case of *Henry vs. the Providence Tool Company*, that the foreign patent cannot be held to include any subsequent prolongation or extension of the monopoly beyond that vested in the foreign patent at the time of granting of the United States patent. This is an important point, as it limits United States patents, granted after a Canada patent has been taken out for the same invention, to five years only, irrespective of any extension which may be obtained in Canada after the American patent has been secured. This point was decided by Judge Blatchford aside from the fact, applicable to this special case, that the defendants had put in a plea to the bill and the plaintiff had set down such plea for argument before the Canada extensions were granted.

NEW SPECTROMETER.—John W. Draper, M. D., President of the Faculty of Science in the University of New York, has invented a spectrometer which will open a new and interesting field to those engaged in the study of spectrum analysis. The ordinary spectroscopic is occupied with the frequency of ether-vibrations or wavelength, while Dr. Draper's deals with the intensity or brilliancy of light, and depends on the optical principle that a light becomes invisible when in presence of another light about 64 times more brilliant. The general conclusions of experiments are that in the prismatic spectrum the luminous density increases from the more to the less refrangible spaces, its maximum being not in the yellow but in the red. In the grating or diffraction spectrum the luminous intensity is equal in all the visible regions, all the colors being simultaneously obliterated by an extinguishing light.

MICROPHONIC STUDY.—Boudet de Paris has experimented with a microphonic transmitter, in which the carbons, instead of being pressed by a spring, are simply kept in contact by a bit of paper folded like a V. It was so sensitive that, with a single Leclanche cell, and at a distance of 500 meters (1,640.4 feet), the receiving telephone reproduced the message so that it could be heard in all parts of the hall. By increasing the amplitude of the vibrations he found that they were of two kinds: 1. Large vibrations, or rather undulations, which always occurred in the same order for any given word or vowel. 2. Small vibrations, very short, very numerous, looped upon the larger ones. He thinks that the undulations are due either to the force of the breath which necessarily accompanies the emission of the voice, or to the inertia of the instrument.—*Comptes Rendus.*

COMPARATIVE STRENGTH OF WOOD AND IRON. Heim finds that, in most cases, a uniform strength of structure can be more economically secured by the use of wood than by the use of iron. The strength of wood is proportioned to its density, and can be increased by its immersion for two or three days, or until complete saturation, in linseed oil, kept at a temperature of from 150° to 212° Fahr.—*Fortschr. der Zeit.*

MECHANICAL PROGRESS.

Transmission of Power by Shafting.

A simple and ingenious arrangement for the transmission of power by shafting has been proposed by Herr Wilhelm Ritter, of Altona, Germany. In order to transmit the motion and power of a shaft, fitted in bearings to one or more shafts, he proposed to place a box or bracket over one of the ends of the motive power shaft, to the outer end of which he fastens a conical wheel. The outer angle of the bracket is likewise formed as a box, the outer part of the boring being enlarged for the reception of a cylindrical prolongation of a similar bracket. It is furnished with a set-screw to secure the second bracket, which can be turned within the enlarged boring of the first one in any desired position of a circle. A short axle passes through the box of the second bracket, the corresponding projection and the box of the first bracket, and to each end of this short axle a conical wheel is attached. One of these wheels is in gear with the wheel of the motive power shaft, while the other conical wheel is in gear with a similar wheel fastened to the end of a shaft that revolves in the boring of the other box of the second bracket. The shaft of the second bracket is thus put in motion, and the axis of the shaft can be turned into any position within the plane of a circle, after loosening the set-screw and turning the second bracket in the boring of the first one. When the shaft of the second bracket has been adjusted, the position of the two brackets to each other is secured by means of the set-screw. Two additional pairs of conical wheels, two other angle brackets of like construction and connection, and another short axle, will transmit the power to a third shaft, and by this means motion and power can be continued to other shafts, the last of which may be constructed for the reception of a tool, or a pulley may be placed on this shaft for driving a tool or implement.

COMMUNICATIONS WITH LIGHTHOUSES.—A new description of rocket, called the "buoyant rocket," has been produced by the Royal Laboratory Department, at the request of the Board of Trade. A rocket was required as a means of communication between the shore and light-houses a few hundred yards from the main land during bad weather, and in circumstances under which the ordinary life-saving rock apparatus by which a line is conveyed to a wrecked vessel would be unavailable. The Laboratory has answered the demand by adopting the old-fashioned Congreve rocket to meet the required end. A small iron tube containing the composition is enclosed in a casing of cork, and fitted to a stick in primitive fashion, with a line made fast to the extremity, and the simple arrangement has admirably succeeded. Three of the rockets have been tried at Shoeburyness, being fired from a trough at the surface of the sea, and plowing a direct course through the water with a strong line attached, by means of which an assistant or a boatload of provisions could be conveyed to the lighthouse keeper.

A VERY SIMPLE PANTAGRAPH.—Schnaus suggests the use of a fine rubber cord, about 15 inches long, supplied with a loop at each end, and having on it a small white bead, sliding on it with gentle friction. By securing one end to the table by a pin, and passing a pencil through the other end, and drawing its point over the paper with the right hand keeping the string stretched, and causing the bead to describe the outline of a simple drawing placed beneath it, a tolerably good copy of the drawing will be produced, bearing any desired proportion to the original, according to the position given to the bead on the string; thus, if the bead is in the center of the cord, the drawing will be double the size of the original. The best results are only obtainable after some practice, and by employing a finer point than a bead.

BOLLEE'S STEAM CARRIAGES.—These carriages carry in the rear a field boiler, and forward, two steam cylinders enclosed in a strong box to protect them against dust. Motion is transmitted by conical gearing to an intermediate shaft, from which the driving wheels are actuated through the medium of chains. Both driving wheels are independent. The carriage is suspended from very long and flexible springs. The front wheels are without springs, each pivoting about its vertical axle like the wheel of a velocipede. On a level road this carriage is stated to travel at a rate of 15 miles an hour, the greatest speed yet made being 25 miles. It is said to be capable of turning curves of 7-foot radius. It is considered in France an important improvement, as it uses only from 2 to 7 pounds of coal per hour, and weighs only 6,500 pounds.

RECORDING THERMOGRAPH.—An ingenious arrangement, capable of being utilized for recording the temperature of mines, has been patented by Mr. Bowkett, of the Leeds Fever Hospital. It consists of a hollow tube similar to that in the Bourdon pressure-gauge bent into a semicircle and filled with a suitable fluid, one end hermetically sealed, the free arm of the other operating a lead-pencil which marks on a dial, moved by clock-work, and which is divided by radii into hours, and provided with concentric circles for indicating the range of expansion and contraction.

PREPARING CARBONS FOR THE ELECTRIC LIGHT.—Prof. H. W. Wiley, of the Purdue University, Lafayette, Ind., in the *American Journal of Science*, says that he found that the American carbons, having a density of only 1.55, against 1.85 for the French, were soft, and were rapidly consumed when used in an electric lamp. He coated them with copper to increase their durability, and tried the expedient of setting a copper wire in the center of the carbons, by which means, it is true, he obtained a steady light, but did not succeed in diminishing the rate of wear. Believing that a way could be devised of protecting the copper coating from oxidation, he tried covering the carbons, after copper-plating, with a film of plaster of Paris about 0.04 inch in thickness. After this had set, the edge of the carbon, which was to be turned toward the condenser, was carefully denuded of its plaster covering, which was also cut away until quite thin on the adjacent surfaces. These precautions were taken so that the plaster might not interfere with the radiation of light in the direction of the condenser. Before use, the plaster must be thoroughly and slowly dried. The copper surface at the end of the carbon being uncovered, it is fastened in the holder in the usual way. The carbons prepared in the way described left nothing to be desired. The light was steady, and the carbons burned slowly away. The film of plaster melted gradually as the point was consumed, and thus never interfered with the illumination. The points of both positive and negative carbons remained blunt, and there was no wasting away of the stem. A carbon prepared in this way will, according to Prof. Wiley, last at least ten times as long as one used in the ordinary way. Its chief advantage, however, is found in the comparative steadiness of the light thus secured.

WIND GAUGE.—A simple apparatus for continuously recording the direction of the wind, constructed by M. Redier, is now in use at the observatory at Lyons. A weathercock of suitable form is supported by a sort of tripod of grooved wheels running upon a circular rail of steel (the wheels having individually a horizontal axis, but collectively a vertical). From the weathercock passes down a vertical rod to connection with a cylinder (placed with axis vertical), which is supported below by a steel pivot resting on a plate of agate, and is guided at the upper part by horizontal pulleys. Thus each movement of the weathercock is transmitted to the cylinder. The latter has wound round it a sheet of paper, graduated vertically and horizontally (the vertical divisions representing the hours, the horizontal the direction), and a pencil applied to the paper is moved in vertical directions by clock-work. It will thus be seen that the tracing obtained on the paper indicates the successive positions taken by the weathercock, and, accordingly, the direction of the wind for any given time.

A VOLTAIC PENCIL.—*Le Technologiste* gives the following description of an instrument which seems to be an improvement on Edison's electric pen: "It is to M. Bellet, a Parisian, that we owe the invention of the voltaic pencil, which perforates the paper in the same manner that it is pierced by Edison's electric pen, but without the intervention of the needle vibrated by a little electro-motor. Instead of actuating a needle as in the ordinary pricking machines used by those who design laces, embroideries, etc., the electric current itself passes through the paper; for, as is well known, the lead of a pencil is a good conductor. This arrangement is advantageous in that the artist sees the traces of his work, his method of working being in no way different from the one which he habitually uses. But more than this, by means of this voltaic pencil, so skillfully perfected by its inventor, the artist, by drawing directly upon the lithographic stone or the metal plate, can now dispense with the services of the engraver, who so often denaturalizes the artist's work."

ELECTRIC INSCRIPTION OF WORDS.—The transmitting apparatus is a microphonic speaker, the carbons of which instead of being pressed by a spring, are simply maintained in contact by the pressure of a small piece of paper folded in the form of a V. The vibrations of the diaphragm of the receiving apparatus cannot be written, since the movements of the style, however delicate the apparatus, can scarcely be distinguished upon the lamp-black. To enlarge the magnetic vibrations of the receiver the cover and the diaphragm of a Bell's telephone are taken away, and on the wood of the instrument there is fixed the end of a small, stiff steel spring. The other end of the spring abuts on the surface of the magnetic nucleus surrounded by its coil; to this extremity is soldered a small mass of soft iron, weighing about 10 grms., and upon this mass and in the produced line of the axis of the spring is fixed a light style of bamboo, 10 centimeters in length and terminating in a slender whale-bone pen.—*M. Beudet.*

A KNOWING ENGINE.—A new automatic pumping engine is in operation at the Providence (R. I.) Water Works. It has 10 cylinders, 5 for water and 5 for steam, arranged alternately in a circle. It possesses an enormous capacity, but it will, without attention from the attendant, do the duty of pumping either for a single faucet or for a dozen steam fire engines. The cylinders are all connected to a single central upright shaft, which automatically either makes 1 revolution in 5 minutes or 25 in 1 minute, according to water required. If the fire burns low the engine will open the damper. If this is not sufficient it will put on the blower.

SCIENTIFIC PROGRESS.

Photography on Wood.

T. C. Harris, in *Practical Photographer*, says: Two many published formulae for photographing on wood are nearly all defective because the block becomes wet during the operation. This is a vital point. Mr. Harris presents two ways of printing on wood which give good results, and do not damage the block in the least. From a negative of the subject desired, make a clear, thin positive on glass, by the wet collodion process. The positive should be of the proper size, on clean glass, without substratum. Tone and fix as a transparency, and lay in a dish of water containing a small percentage of sulphuric acid, to loosen the film. The film will soon become so loose that it can be easily stripped from the glass and transferred to the block. To do this, lay on the film a piece of wet albumenized paper a little larger than the glass. Press out the bubbles and surplus water carefully, then turn back one corner of the paper, and it will come off, bringing the film with it. Have the block smoothly whitened with Chinese white in gum water, and the surface slightly damp. It is now easy to transfer the film to the wood and remove the paper, when the block must be allowed to dry spontaneously.

Another way to print on wood is by a sort of photo-lithograph process. Coat paper with a thin, uniform coat of gelatine in warm water. Dry, and float a short time on a weak solution of bichromate of potash in water. Dry again, and expose under a negative till all the details are visible. Now roll the entire surface of the print with a printer's roller charged with lithographic transfer ink thinned with spirits of turpentine. Now soak the paper in a dish of tepid or warm water until the ink can be removed, by rubbing gently with a small sponge. All the ink, except the lines composing the picture, can be removed, when the print should be laid face down on the whitened block, and subjected to a heavy pressure in a common letter-press. The paper can be easily removed by wetting the back.

Another application of photography as a help to the engraver was discovered by the writer. Procure hard rubber, in smooth, black, polished sheets of about one-eighth of an inch in thickness. These are to be cut to the proper size, cleaned and albumenized the same as glass for negatives. The rubber plate is covered with collodion, sensitized in the bath, exposed in the camera, and developed in the usual way of making a negative. In fact, the whole operation is exactly the same as in making a ferrotype on rubber instead of an iron plate, and a ferrotype bath and collodion are well adapted to the rubber. When a clean, sharp image is obtained, it is fixed in cyanide and varnished with a thin, transparent varnish, and dried by a gentle heat. The plate is now ready for the engraver, who will have a fine smooth surface and a clean drawing to work on.

When engraved, the plate is mounted on a wood block, and made type high, and is ready for the printer. The rubber is somewhat more difficult to engrave on than box-wood, but the surface is much finer, and makes a more durable printing block. Unless more than one cut is desired, it is unnecessary to have it electrotyped, as wood cuts are, but the original can be used in the press along with type, and as many as 75,000 to 100,000 impressions taken from it before it shows wear.

THE TELEPHONE AS A LIGHTNING INDICATOR.—Mr. George M. Hopkins, of Brooklyn, N. Y., during a recent thunder storm connected the gas and water pipe of his dwelling with an ordinary Bell telephone, and discovered that the electrical discharges were plainly indicated, either by a sharp crack or by a succession of taps. This occurred when the discharge was so distant that the thunder was inaudible. The sound also seemed to be perceived by the ear before the lightning could be seen. There was a marked difference in the character of the discharges, some that appeared single to the eye were really multiple. Often the discharges would consist of a series, beginning and ending with discharges larger than the rest, thus: — — — — —, sometimes it would be thus: You will have to use small turned rules, and thick ones — — — — —, sometimes the reverse, and often a single crack. The gas and water pipes were used, being the most convenient and at the same time the safest conductors for the purpose. Special apparatus might be devised, having a good ground, and a series of points for gathering the electricity from the air, but in using apparatus of this kind there is always more or less danger.—*Scientific American.*

IMPROVEMENT IN SUGAR MANUFACTURE.—A sugar planter and manufacturer sends the *Martinique Bienpublic* an account of an experimental application to sugar cane of the diffusion process employed in the beet-sugar factories of France and Germany. The experiments were made at the plantation Moncepos, Guadeloupe, with an apparatus of six macerators. It was badly adapted to meet the difficulties incident to the peculiar nature of cane, yet it showed (1) that by a methodical washing of the slices of cane an artificial juice nearly equal in density to natural cane juice could be obtained; and (2) that one hour of systematic maceration is sufficient to completely exhaust the cane fiber of the sugar which it contains.

THE ROBERTSON PROCESS.—The results of the trials of this new process, so far as it has been tested on ores from this county, indicate that it will actually accomplish what we have so often been promised, a wonderfully beneficial "revolution in quartz mining." A short time ago Mr. Parkinson, an "expert," paid \$15 per ton for ten tons of ore from the Rose mine, this city, which Mr. Brewster, proprietor of that mine, could not make pay more than \$7 to \$8 per ton by ordinary mill process. This ten tons of ore was sent to Sacramento, and there worked by the Robertson process, and yielded \$382.50, or \$38.25 per ton. A lot of about eleven tons from the Gold Deposit mine, Kelsey district, which was rated as about \$25 to \$30 rock by ordinary mill process, was sent down to Sacramento, and yielded about \$1,200, or \$110 per ton by the Robertson process. A small six-pound sample of Gold Deposit ore yielded \$107.15, or at the rate of about \$35,000 per ton. It is confidently claimed for this process, and the above results seem to justify the claim, that it will save all the gold there is in the rock. And, best of all, an outfit for reducing ore by this process can be obtained at vastly less cost than attaches to the old style.—*Mountain Democrat.*

MAGNETS IN THE MILLS.—The introduction of magnets into all the great mills of Minneapolis and a great many elsewhere, says the correspondent of a Chicago paper, has been a revelation to the millers who complained of wire in wheat. Not only have the magnets captured all the stray pieces of iron bands, and thus removed the last and only objection urged against wire binding harvesters, but they have revealed the startling fact that of the scraps of iron and steel that find their way to the mills mixed with wheat, fully one-half are something beside pieces of wire, and a larger proportion of which are of such a nature as to be even more dangerous to mill machinery. The magnets gather everything of this kind with the certainty of fate, and millers are free to acknowledge that their introduction is a blessing the value of which cannot be overestimated. The device is so simple and cheap, and the remedy for the evils complained of is so complete, that farmers and manufacturers will never again hear any complaints from millers, growing out of self-binding harvesters and wire bands.

PRESERVATIVE WRAPPING AND PACKING PAPER.—Mr. John F. Rodgers, of Philadelphia, claims to have discovered a preservative wrapping and packing paper for protecting cloths, furs, etc., from mildew and ravages of moths and other insects. The patent bears the date January 9th, 1878. The paper used is made from woolen and cotton rags and manila rope or manila paper. This paper is saturated with a mixture of 70 parts, by measure, of the oil remaining from the distillation of coal tar naphtha by live steam with five parts crude carbolic acid, containing at least 50% of phenols, 20 parts of thin coal tar, heated to about 160° Fah., and five parts of refined petroleum. After saturating the paper it is passed through squeezers and over hot rollers for the purpose of drying. When cool it is cut into sheets as desired, and the drying completed in the atmosphere. The paper thus treated is used for packing woolen clothing, cloths, furs, carpets, and all material likely to be injured by moths, mice, or vermin, and will also to a great extent, he states, prevent cotton material from mildew.

LIGHTNING RODS.—Mr. R. S. Brough has been discussing, in the *Philosophical Magazine*, the proper sectional areas of iron and copper lightning rods. So far as mere conductivity is concerned, a comparatively thin wire of either metal would suffice for any conductor; but such a thin conductor would be dangerous, because it would be fused by a heavy discharge of lightning. Iron being more liable to be fused than copper, Mr. Brough sought to determine the relative sectional areas of rods of two metals, so that neither would be more liable to fuse than the other. Ordinarily, it is stated that the iron rod should have four times the sectional area of the copper rod. Mr. Brough shows that these areas should be as eight to three; or since the rods are invariably made circular, and circular areas are to each other as the square of their diameters, the diameters of iron and copper rods of equal effectiveness should be in the proportion of 1.63 to 1. Iron is, therefore, much the cheaper metal for lightning rods.

THE MONT VENTOUX METEOROLOGICAL OBSERVATORY.—Some time ago M. Bouvier, Engineer-in-Chief of Bridges and Highways in the Department of Vaucluse, took the initiative in advocating the construction of an observatory at the summit of Mont Ventoux. Considerable subscriptions in aid of the good work have since flowed in from friends of agriculture and of science, and at its last meeting the Conseil General of the Department, at the instance of M. E. Raspail, voted a sum of 20,000 francs towards the construction of a road giving access to the site. The contemplated work may now, therefore, be considered on the high road to success, and its completion will be regarded as a subject of legitimate congratulation, for an observatory at this point should furnish valuable data, which, combined with those collected at Pic-du-Midi and Puy-de-Dôme, will render complete the system of meteorological studies for the whole of the south of France.

MINING SHAREHOLDERS' DIRECTORY.

The Mining Share Market.

Operations at the several stock boards drag at a doleful rate. Prices of shares have gone down, down, till dealers "in the lowest depths see lower depths still opening to devour them." Margins disappear at a rate that threatens to break brokers and burst their clients. The whole fraternity are being impaled on the ragged edge of despair, or the almost equally uncomfortable forlorn hope. In Comstock securities the dullness is especially noticeable, is, in fact, appalling. Developments here are fearfully delayed. Prices tumble, but expenses keep up, and production shrinks while assessments grow. Dividends are in the inverse ratio of disbursements, and so the outlook is panicky, adumbrating managements of the necessity of supplementing pluck with economy and discretion. That these Comstock directories possess the hold on principle, is undeniable; but while perseverance is commonly a good thing, it is none the less a virtue for being sometimes tempered with moderation. Nevertheless, while business sense is, in the main, desirable, to one whose mission it is to huck against stone walls, the less brains the better. In this depressed state of the market brokers must needs be put to their wit's end to make expenses. In this emergency the craft would do well to take counsel of good Isaac Walton, who counseleth his disciples after this wise, "when ye sucker becometh over shy in one pool, then do ye thereupon fish elsewhere, and if ye gudgeon refuseth to hite at the bait in use, get ye other whereof he woloth not, for whiles this sort growth that shy, that angling for him becometh a vexation and a vanity," which being translated into modern language, and interpreted for brokers' use, means that they would do well to change their tactics or introduce some new gambler to tempt the cupidity of the avaricious, and ensnare the unwary. To such as can hold, however, recourse to the expedients suggested may not be necessary, as the prices of stocks will no doubt come up again after a time, and the market boom as of old.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Indian Queen, July 15th, \$3,278.43; Alexander, July 18th, \$6,823.97; Northern Belle, July 14th, \$2,618.99; Mammoth, July 13th, \$14,038.97; Independence, July 21st, \$12,600; Belle Isle, July 21st, \$33,700; Hillside, July 21st, \$4,200; Northern Bell, July 19th, \$4,361.83.

THE REVOLVING GRAIN CAR.—Some time ago we alluded to the design of an Eastern inventor who proposed to transport Western grain to the East in revolving cars—cylinders that rolled along the track as they were pulled by the locomotive. We now learn from the *Prairie Farmer* that preliminary tests of these cars have proved satisfactory. One came into Chicago full of corn. Major Fitch, the state inspector of elevators, says: "The grain is in perfect order and is improved if anything by being transported by the new system. This car was not loaded quite full, lacking probably 10 or 15 bushels. I regard the car as an undoubted success." We are informed that among the points demonstrated by the trip were the following: The rate of speed required for permanently holding the grain to the shell by the centrifugal force, thus forming a solid cylindrical mass, preventing all attrition of the grain, was found to be about four miles per hour. Second, the perfect circulation of the air through the grain while in transit; also the effect of having the cylinders only partially filled, which was found to be in no way detrimental to the grain or car.

A WASHOUT, Ogallala station, 30 miles west of Omaha, on the U. P. R., delayed trains 12 hours on the 21st.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ITEMS.—*Mercury*, July 19: The Onelda mill is running 40 stamps. There is a fair-sized body of ore in the lower drift, and mining matters here have done for months. The Keystone mine, at Amador City, is getting in immense quantities of fine wood. A large number of teams are engaged in hauling. Work has been resumed on A. M. Vaughn's claim at Plymouth. The shaft is now down about 200 ft, the ledge being two feet wide, and the rock rich, paying \$25 per ton by mill process. They are pushing work on the Lucky Baldwin in Hlg canyon. The hoisting works are up, and a full force of hands are making things lively in that old mining camp.

Volcano.—At the Downs mine another clean-up was had last week, resulting even more satisfactory than previous runs. The quantity of rock crushed is estimated at 144 tons, and from this the output of gold was \$6,300, over \$15 per ton. A new shaft is being sunk, which will be completed in the course of a week or two. Another quartz discovery has been made in the Volcano district, which bids fair to rival the famous Downs mine. W. Q. Mason is the lucky prospector. He has been prospecting around for 10 years past, and two weeks ago struck a quartz vein on the Welsh branch of Sutter creek, about three miles from Volcano. He was led to the discovery by some rich float rock picked up on the surface. The ledge is small, like all the rich pocket leads met with in that country. As far as opened it shows eight inches wide. The richness of the rock is something extraordinary. Mason pounded 70 pounds in a mortar and obtained \$42 in gold; he subsequently crushed 60 pounds and got \$32.

BUTTE.

OLD BANNER.—*Mercury*, July 18: This mine, which was caved in 20 years ago, has been reopened by a shaft sunk 200 ft; then a crosscut of 50 ft, from which an incline was excavated a distance of 55 ft. The history of the mine prior to the cave warrants the belief that rich ore will be found.

CALAVERAS.

ITEMS.—*Chronicle*, July 19: In Negro gulch, in the vicinity of George Leavitt's ranch, they have discovered a quartz vein, averaging three feet wide, that prospects \$100 per ton. We do not know how far development has progressed, but enough work has been done to demonstrate the fact that the ledge is one of the most promising ever discovered in the county. Everything is going on in a grand way at the mining. In the 1500 level the ledge has narrowed down to 3 or 10 ft, and the ore increased in richness.

EL DORADO.

ITEMS.—*Democrat*, July 19: The Springfield is turning out very fine specimens of ore, and there is every indication of the next 700 ft surpassing in richness the last. A new shaft has been put in working order at the Old mine. Drifting on the ledge of the Central mine shows fine ore. A new pump is being put into the Tingham mine.

MONO.

Bodie Cox.—*Standard*, July 15: The crosscut east from the old shaft, on the first level, is in 374 ft. The drift south, on ore, second level, is in 92 ft. The main east crosscut, third level, is in 267 ft. The east drift on the Standard line from north drift No. 1 is in 28 ft. The north drift No. 2, same level, is in 174 ft. The south winze is down 41 ft. The old north winze is down 46 ft. The new north winze is down 14 ft. The vein in the bottom of the old north winze contains very fine in quality and size. They have not yet cut the vein in the new north winze, not being quite deep enough, but expect to be into it very soon. On the second level the vein is looking well and yielding very good ore, and on the first level the vein is improving very much in appearance and also in quality. The mill has been running steadily during the week.

Queen Bee Mine.—This mine is situated on the western side of Queen Bee hill in Bodie district. The last Chance is 1,500 ft long and a ledge within its lines has already been developed a length of 600 ft by means of incline shafts 40 to 70 ft in depth. Ore from this ledge yielded \$30 per ton.

NORTH FORK DISTRICT.—*News*, July 20: About 15 miles west from Mammoth City, Elko district, is located North Fork Mining district on the headwaters of the San Joaquin river, which takes its rise there. Information received from there represents the country as being extensive in ore production, and the ledges large and well defined. The formation is of porphyry and granite, and the mineral of the black sulphur character. Mr. Wiesner, a gentleman doing business at Mammoth, and just returned from a prolonged visit to one of the mines, brought with him several valuable specimens of rock, assays from portions of which went as high as \$14,000 to the ton in silver.

STANDARD.—The north drift from the east crosscut, 386 level, is in 283 ft; progress since last report, 11 ft. The upraise on ledge is up 225 ft; progress during the week, 10 ft, and the ledge here is about 12 ft wide of very fine ore. The ledge in the south drift is 15 ft wide of very good ore. West crosscut from the south drift, 450 level, is in 143 ft. The winze in west crosscut from 550 level is down 30 ft; the ledge here is 10 ft wide of good ore. Have upraised on this ledge 25 ft, showing about eight ft of very fine ore. In the West Standard stope the ledge is nine ft wide of the usual rich ore. In the south drift, 300 level, the ledge is six ft wide and looks well. In the stopes, south drift, 550 level, the ledge is about eight ft wide of good ore.

CROSSCUTS.—The vein, which crops out boldly in the Syndicate ground, has been traced thence the entire length of the Crosscut claim, and shows a width of two ft at a depth of 300 ft from the surface, being the lowest point at which work has been done on this ledge. Assays taken during the past week show very good results in gold and silver.

ORO.—This mine adjoins the Addenda on the east, the Oodshaw on the north, and the North Noonday on the west, and embraces 200 ft in width (having purchased the area) and 1,500 ft in length. The vertical shaft sunk as a double-compartment one, and has been rapidly pushed down to a depth of 240 ft. At 55 ft from the surface a ledge was cut carrying quartz, being 15 ft wide of very good ore. At 15 ft and other very was cut which carries gold and silver ore, the latter predominating.

UNIVERSITY.—Old works closed; new shaft down 25 ft. The ledge has been traced from the croppings at the mouth of the old shaft up the hill to the new shaft and beyond, and is now being followed south for the purpose of proving the ground. Engine and boiler for the new shaft has been ordered and will arrive.

SYNDICATE.—There are now over 600 tons of ore cut down and in the chutes ready for transmission to the mill as soon as the present contract with the Standard company is completed. Assays from the breasts and old stopes continually improve as progress is made. A splendid ore dump is being built at the mine, which will permit the ore to be shipped directly into the battery hopper without extra handling.

SUMMIT.—The north drift, 200 level, is in 201 ft; progress during the past week, five ft. The ledge is two feet wide. East crosscut from this drift is in 163 ft. The south drift is in 134 ft; progress for the week, 21 ft. The ledge is three feet wide. It will cost about \$1,500 to repair the shaft, house, etc., which was damaged by the explosion. North Branch—Good headway is being made in sinking and timbering the new joint shaft. The formation in the bottom is changing for the better, being full of ledge matter and quartz of a fine character. Assays continually improving as progress is made.

TIOGA.—The winze on the 320 level, on the Yerrington vein, down 119 ft; ore improving as depth is gained.

SOUTH BUTLER.—Ledge looking well and increasing in strength, and is now three feet wide of good ore.

GOODSHAW.—East drift is now in 430 ft and still progressing at the rate of three feet per day. The formation is of quartz and porphyry.

BRACKENBURY.—East drift on the 320 level in 135 ft; line formation. Winze, same level, on Warren ledge, down 95 ft on the vein, which shows four ft of fine rock. North drift on same ledge in 125 ft; looking well.

NORTH STANDARD.—The strainers and strata of fine-looking quartz increase in width with every ft sunk.

BUTLER.—The south drift, 350 level, is in from the east crosscut 100 ft; progress since since last report, 10 ft. The ledge is three feet wide of good ore.

VORTEX.—The winze from the north drift on the 290 level has now attained a depth of 15 ft. The ledge in the bottom is three and one-half ft wide, of splendid ore, and is improving in quality as depth is attained. Good ore is now being hoisted daily to the surface which can be milled at a very handsome profit.

BAR TEXAS.—The shaft is about 1,000 ft and a new contract has just been let to run a further distance of 100 ft. Are at work drifting on the vein at the 900 station.

MARYLAND COX.—South drift is now in 40 ft, and the north drift 82 ft. The flinty boulders encountered has been passed through and better material encountered beyond it.

SOUTH BODIE.—East crosscut, 500 level, is in 197 ft, 20 ft having been made during the past week.

NEVADA.

ITEMS.—*Transcript*: The Idaho mine is running its full head of 50 stamps. Work is about to be commenced on the Sneath & Chy mine. The Nevada Foundry is filling a large number of orders for mining machinery. The Oriental Con. is to be supplied with a 20-stamp mill. New mining works for the new shaft of the Merrifield and Constitution mines are completed. The latter mine is near the Munchie, and is yielding very rich ore.

WASHINGTON.—*Football Tidings*, July 19: The Last Chance mine, on Diamond creek, about eight miles above the town of Washington, has a fine prospect in the upper tunnel. They have just cut the ledge, which is from 14 inches to 21 ft in thickness and shows well in free gold and sulphurets. The lower tunnel is within 30 ft of the ledge, which it will cut at a depth of 80 ft from the surface. This property is finely located and has extensive croppings which themselves prospect well in free gold and sulphurets. Osborne & Co., on the southern extension of the Last Chance, are now building reduction works at their mine, including a Robertson furnace and process, and expect to have them in operation in about two weeks. The Bessie Miller company have resumed operations at their mine, repairing the old tunnel, building shop, cabins, etc. Orissel & Co., a short distance above Rocky Bar, are putting in a large flume, and getting ready for work, and several other companies are also busy preparing for this class of mining. In the Deadwood mine, 3,000 ft of pipe have been put in to convey water from the Snow Mountain ditches for the machinery of which is run by a hurdy. A pressure of 304 ft is given, with a stream that measures 22 miner's inches. The south drift on the 400 level is in 230 ft, showing a pay chute for 200 ft of that distance. The ledge is from one and a half to three feet thick, and a crushing of the rock recently made, yielded about \$60 in free gold per ton, while one-tenth of the mass is composed of sulphurets. The Lyle Yankee mine, situated between the town and Nevada City, has its shaft now down 120 ft on the ledge. The rock at this depth is much better than was expected. The ledge is 13 inches thick, and very heavily charged with sulphurets and galena—some miners computing it as high as one-half.

ROCKY BAR MINE.—*Union*, July 20: The water has been pumped out of the Ghanavine shaft preparatory to connecting a drain drift thence to the North Fork Hill mine. The incline was found to be 317 ft deep to the 3d level, with a sump 16 ft below. Quartz of a fair quality is found in the drifts and stopes of the 3d level, and tributors have been set to work to extend the old drifts both east and west. A survey of the ground shows that the drain drift will have to be run a distance of 140 ft—90 ft in the Rocky Bar and 50 ft in the New York Hill ground, to make a connecting line of drainage, thence from the bed of Wolf creek to the hoisting shaft of the Rocky Bar, the ledge keeps its usual size and good quality, and everything about the mine is running satisfactorily.

PLACER.

ITEMS.—*Herald*, July 10: Mining operations in this section for the month of June have been generally favorable. Numerous prospecting operations commenced earlier in the season are showing very favorable results, and several new claims will commence work preparatory to more extensive operations at the opening of the season in the spring.

SACRAMENTO.

ITEMS.—*Folsom Telegraph*, July 19: W. H. Dolman, of Oakland, has secured a lease from the Natoma W. & Mining Co. of several hundred acres of the most favorable ground, on the American river, near Folsom, and is now looking ready to commence the machinery of which is run by a hurdy. A pressure of 304 ft is given, with a stream that measures 22 miner's inches. The south drift on the 400 level is in 230 ft, showing a pay chute for 200 ft of that distance. The ledge is from one and a half to three feet thick, and a crushing of the rock recently made, yielded about \$60 in free gold per ton, while one-tenth of the mass is composed of sulphurets. The Lyle Yankee mine, situated between the town and Nevada City, has its shaft now down 120 ft on the ledge. The rock at this depth is much better than was expected. The ledge is 13 inches thick, and very heavily charged with sulphurets and galena—some miners computing it as high as one-half.

SHASTA.

ITEMS.—*Courier*: The quartz mill at the Mad Ox, seven miles above Whiskeytown, is running day and night, the parties are confident of a good thing in their mine, which is well located with a large body of fine-looking quartz now in sight. The extension of this mine, known as the Peckham mine, now owned by A. S. Sauter, Wardell, Scott & Co., is turning out a large amount of good quartz. It is worked by an arastra, and pays from \$100 to \$140 per ton; ledge from three to five and a half ft in thickness. On Mad Mule, W. Banghart is working his seam diggings very quietly, but with very satisfactory results. Since 1860 he has his new tunnel in 500 ft, and is within a few feet of his pay chimney or seam, which is very rich. Eschever's Jackson is working the extension with good results. The diggings have been very rich in the gulches in this vicinity in past years. The Bell & Knox mine, in Orizzly gulch, in same district, has yielded a large amount of gold during the past two years.

FRENCH GULCH.—The mining interests around French Gulch are very encouraging. Messrs. John Souter, Syme & Co. are getting the old Washington mill and mine in running order again, as they have found new bodies of ore. The quartz in this district is good bearing. F. McGonnell and H. Dorr have a fine prospect higher up the mountain; their ledge is between slate and porphyry, rock averaging from \$40 to \$70 per ton, worked by an arastra right at the mine. V. Kearns is also running an arastra on the north fork of the creek with equally good results.

SIERRA.

ITEMS.—*Mountain Messenger*, July 19: Some fine-looking dust has just been brought in from Craycroft hill. Mining machinery for the Alaska mine, near Plum valley has arrived, and mine will shortly be worked.

TRINITY.

DEADWOOD GULCH.—*Journal*, July 10: Passing over the mountain, from Shasta county, at an altitude of 4,100 ft, into Trinity county, we find Deadwood gulch, on which five arastras are now running—George Klein two, G. F. Deiner two, Waver Sebastian one. Mr. Wiley and Mr. Davis are also working very rich ore from their mines. Ores in this district run from \$70 to \$120 per ton, and some have run even higher than this. This district, well located, formation slate and porphyry, the same French Gulch district, and the gold of good quality.

NEVADA.

CON. VIRGINIA.—*Old Hill News*, July 23: The output of ore from the mine has been nearly doubled of late and the yield of bullion will be correspondingly increased. Four ft per day are being added to the length of the west

joint crosscut, 850 level, and harder rock is encountered. Winze No. 2 on 1650 level is being reopened for ventilation. Crosscut on 2150 level is in 40 ft, cutting good vein material showing some quartz.

ORUHA.—The main incline is 135 ft on the slope below the 2200 station and still continues in a likely, vein formation, carrying streaks of low-grade ore. The east drift on the 2200 level is in most promising vein material carrying stringers of quartz and low-grade ore. The raise from the drift north of No. 1 winze is 52 ft up and in low-grade ore. The raise south has connected with stope above.

JACKSON.—The ore stopes on the 950 level are yielding the usual quantity of good rock, and for the past few days there has been a little improvement in the quality. Crosscut No. 2, west, 1500 level, has cut the clay and is encountering streaks of ore and nice vein porphyry mixed. The ore assays about \$30. As this crosscut is advanced the formation grows stronger and better and an increase of water is encountered. Crosscut No. 3, east, on the same level, is cutting through streaks of ore which assay tolerably well.

BRECHER.—The main incline is now 150 ft, on the slope, below the 2200 station. Since the connection on the 2700 level with Crown Point ventilation has been greatly improved. The drift south on the 2700 level will be continued along the west side of the vein to the south line of the mine. The station at this level is being cut out and timbered, which work will occupy some 10 days yet. Crosscut No. 1, 2600 level, is cutting fine-looking quartz.

ALTA.—Sinking the incline has been resumed. The 500 drift, 750 level, has passed through a strong stringer of quartz and continued in vein material without any sign of a footwall. The north drift, 1550 level, in Lady Washington ground, continues to cut clay and quartz with stringers and bunches of ore running from \$5 to \$11. The 350 tons of ore which crushed the old ore dump will be hauled to the mill for reduction, and when the new ore house is completed a raise will be made in the ore level from the 1450 to the 1350 level and the ore stope opened.

UNION COX.—The east drift from the main north drift, 1000 level, to connect with the Union shaft, is in 110 ft, in vein porphyry carrying an increase of water which makes progress slow.

CALIFORNIA.—The joint crosscut west, 850 level, is cutting harder rock, its face 452 ft from the initial point. On the 1350 level, preparation is being made for opening a drift north from crosscut No. 1 to reach the ore stopes on that level.

UNION SHAFT.—The 1900 station is opened and connected with the drift through from the Ophir incline, 2000 level, and sinking has been resumed. From the shaft a drift has been started west on a level corresponding with the north drift in the west, and the machinery of which is run by a hurdy. The surface of the foundation for the pump hoist is being put in and the excavation for the large pumping engine is being made.

LADY BRVAN.—The east drift, 750 level, is in 120 ft, and in softer ground. The west drift, same level, continues in hard rock. The east crosscut from the south drift is also in quartz giving low assays, and the east crosscut from the north drift is in hard rock. On the surface the foundation for the pump hoist is being put in and the excavation for the large pumping engine is being made.

SIERRA NEVADA.—The water in the incline and from the stopes has been decreasing of late very slightly. The north drift from the 2300 station is in 18 ft, showing some quartz, and chutes are being cut for this level.

TROJAN.—The drift west from that north, on the second level, is in 65 ft, and is cutting quartz and porphyry.

NIAGARA.—In the north drift the formation is hard and progresses slow. These drifts have been extended 57 ft since last report.

ANDES.—West crosscut, 350 level, has cut some fine-looking quartz and found considerable water.

NEW YORK.—The crosscut on the 1200 level is penetrating quartz, and the bottom of the incline is in softer ground.

ALTA AND BENTON.—*Enterprise*, July 23: At the south end Alta and Benton are looking well. Some very rich ore is being found on the 1350 level, and crosscutting is in progress at the 1750 level and other points. The Briggs mill is running on ore from these mines. The drift in Lady Washington on the 1550 level is beginning to get into ore.

ITEMS.—The 2100 level of the flooded mines was drained last Monday. Thus far the donkey pumps at the Hale & Norcross have not been started up, but will start to-day. The Savage folks will soon start up their third donkey pump. They are also running their big main pump. The work of sinking at the Requa shaft has been resumed and is making rapid progress. There is no water at the bottom to interfere with the operations of the workmen.

ARIZONA.

ITEMS.—*Arizonian*, July 12: The force on the Prince and Black Warrior, some 35 men, are all at work on high-grade ore, which is being packed to the Pecked mill for reduction. The mine is opening finely, and bids fair from present development, to become the leading mine of Yavapai. The vein is large and the ore of a high grade, and there can be no doubt that as depth is attained, sufficient water will be found to run a mill. Hoisting machinery has been ordered for the Peck, and as soon as it arrives sinking the main shaft will be resumed.

TIGER.—Sinking of the main working shaft is making rapid progress, the work being done in first-class style. The stopes from the old shaft are all in fine ore. The supply of water from the mine keeps the mill steadily at work. Some 50 men are employed at the mill and mine. Besides the discovery claim on the Tiger now worked, there are a dozen others looking equally as well. Owing to the scarcity of water, operations have been suspended in the Oro Bonita mine. The mine is looking well.

TIPTOP.—One hundred and twenty-five men are employed at this mine, turning out the regular ore supply daily. This valuable property is showing up finely. The bottom of the main shaft—400 ft deep—is in high-grade ore. The mine is turning out about \$35,000 per month. Messrs. Groom & Dunn have a fine prospect on the Pecked. The ledge is said by parties who have visited it, to equal anything in the district. The last lot of ore worked at the Tiptop mill yielded at the rate of \$500 per ton.

GOODWIN.—Holmes' claim, on the Oodwin, shows a magnificent body of rich ore nearly two feet wide, and worth \$300 per ton. The Oodwin is steadily improving as depth is reached, the vein becoming larger and the ore of a higher grade.

SENTINEL.—July 10: Last Sunday's train took the third shipment from the Tombstone mill, of 10 bars, valued at \$22,517.61, also 18 bars from the Tiptop mine, valued at \$30,232. There was a partial clean-up at the Yuma mill last Saturday. The tailings washed from the blankets were not cleaned, and from assay are assessed to contain about \$1,000. We are told this partial clean-up was a result of about \$10 per ton, which, considering the very small expense of mining and working, is very satisfactory.

ITEMS.—*Globe Silver Belt*, July 18: The owners of the Manzanita made a working test of a ton of ore without selecting which gave returns of \$27.65, worked out with a rudely constructed arastra. The ore, the Chamberlain mill, the development so far, is in shaft No. 1, sunk on the north-east end of the claim 40 ft, from the bottom of which there is a level run southwest 40 ft, which exposes to view a vast body of high-grade ore three and one-half or four feet wide nearly the entire length.

BRITISH COLUMBIA.

CASSAIR MINES.—The latest advices from the Cassair mines, dated Victoria, July 22d, are of a more encouraging character than any that have been received for some time past. Many of the claims on Deford creek are paying well, and from one of them two handsome nuggets, weighing respectively 45 ounces and 15 ounces, were recently taken out. A letter dated Fort Wrangle, July 10th, states that Mr. J. Galbraith had arrived at that place with \$15,000, and Johnson, the express carrier, with \$10,000. Leiser & Go. had also made a shipment of some \$12,000. It is stated, on good authority, that more money has come out of the mines this season than was taken out during the

The Absorption of Hygroscopic Moisture by Cereal Grains.

(Graduating Thesis of EDMOND O'NEILL, College of Agriculture, University of California.)

It is well known that all substances absorb moisture from the air. The effect of this is seen in the swelling and curling of animal and vegetable substances. This is the principle on which cat-gut and horse hair hygrometers are constructed. The moisture thus attracted, is deposited in an exceedingly thin film, not apparent to the eye or to the touch. Even substances like polished metals and glass are thus covered with an invisible coating of moisture, as is made apparent by weighing the glass, wiping it with a dry cloth, and again weighing. The second weight is invariably the smaller, owing to the removal of the film. On standing, more moisture is attracted, and it resumes its former weight. The presence of this film may also be shown by writing on the glass with any object. This will remove the film, and, on breathing on the glass, the writing will become apparent, on account of the amount of condensed moisture being less on the places where the film was removed. This phenomenon is often a cause of considerable error in weighing large pieces of apparatus.

The cause of this absorption is the physical attraction between the aqueous particles and the particles of the substance. If the substance be either porous or capable of entering into chemical combination with the water, much more will be absorbed than in the case of glass. A porous substance, like brick or charcoal, will increase in weight many times more than a piece of glass of the same size, merely on account of the larger surface. Some substances, like nitrate of sodium, or chloride of calcium, will continue to attract moisture until they form a liquid. Substances like sulphuric acid and phosphoric anhydride, which form a chemical combination with the water, will attract every particle of moisture from a limited volume of air, as a new surface, capable of attraction and combination, is always presented.

Grains, seed, flour, cloth and even oils, absorb considerable amounts of water. In Europe, valuable substances like silk and wool are always sold with an allowance for contained moisture. The temperature and humidity of the atmosphere are observed, and, by means of tables previously determined by experiment, the amount of water in the silk obtained. It is often considerable at 55° Fahr., being about 15% (Knop.). This absorption property is of great importance in the case of soils. Davy maintained that the fertility of a soil was proportional to its hygroscopic power. This, however, is not always true. The absorbent power is generally proportional to the porosity or fineness of division. According to Schubler, coarse, silicious sand, exposed to a saturated atmosphere, absorbed nothing in 72 hours; fine calcareous sand, three-tenths per cent; clay, 8%; and humus, 12%. This shows the effect of fineness of division; but soils containing humus and clay are generally fertile, which explains Davy's proposition.

In California, this absorbent power is practically noticeable in the case of the cereal grains. The bulk of these crops are raised in the interior of the State, and generally stored there for some time. The climate in summer is extraordinarily dry, and the grains will give up nearly every particle of moisture. When removed to San Francisco and stored in damp warehouses, or shipped to a foreign port in the hold of a vessel, where the atmosphere is nearly saturated, the weight is materially increased. It has been said that this additional weight will pay the entire cost of freight from San Francisco to Liverpool.

This absorbent power has been noticed very often, especially in California. A writer in the *Pacific Rural Press* mentions the fact that the lower sacks stored in a warehouse gain a considerable amount. The reason that the lower ones gain more, is that the moisture, which generally comes from below, is almost completely absorbed by these lower layers, none being left for the upper ones. Another person mentions that the outside sacks of a pile of freshly threshed grain standing in the field for 10 days weighed 30 pounds less than the inner sacks. Freshly threshed grain always contains moisture, and it was the loss of this which caused the difference. The time, being only 10 days, was not sufficient to allow the inner layers to dry out. Several other instances have been noticed and they all agree that the grains may gain or lose a very large amount in a comparatively short time.

As many inquiries have been made as to the actual amount that could be gained or lost, and to whom the profit went, experiments were made to determine these points. It would be very important to the farmer to know whether it would be profitable to store his grain, or to sell it off the field; whether the commission merchant should take the farmer's weight, or to weigh it himself in San Francisco. All these points are of the greatest practical importance to the grain raiser of the State.

The amount of absorption may be measured in several ways. Among the oldest and not very accurate ones are those of Leslie. The substance was dried at as high a temperature as possible

without changing it, placed in a flask with a small opening, and the whole exposed to a saturated atmosphere. The amount of moisture in the small flask was measured by means of a delicate hygrometer, and this was assumed to be proportional to the amount absorbed by the substance. In this way he obtained the relative absorptive powers of a great many substances.

Schubler's method was to place the substance, previously dried at a temperature of 100°—200° C., on a small table standing in water, and to cover the whole with a bell-jar. The increase of weight indicated the amount of water absorbed.

The defects of this method were, that the layer of substance was too thick, the time of exposure not long enough, and with his appliances the atmosphere not fully saturated. This latter was proved by Knop, who showed that moistened filter paper loses weight when exposed to an atmosphere like that employed by Schubler.

The method adopted by me was Schubler's, as modified by Prof. Hilgard. The bell-jar was made as low as possible, and filter paper, dipping into the water below surrounded the substance, which was spread out in as thin a layer as possible. Even with these precautions, the grain will continue to absorb for a period of from 12 to 18 days.

Since temperature changed the amount of water in a saturated atmosphere very much, the apparatus was placed in a room where the temperature was constant, about 18°.

Experiments according to this method were made with wheat, barley and oats. About 25 grammes of each were employed, spread out on large watch-glasses. The weighings were made in a corked flask, as the grain lost weight rapidly when removed from the apparatus. The absorption was accompanied by considerable swelling, which, however, was not measured.

The following table shows the percentage of moisture absorbed by air-dry substances from a saturated atmosphere, the temperature being 18° C.:

	Oats.	Differences.	Barley.	Differences.	Wheat.	Differences.
8 hours....	3.80	7.79	3.52	7.00	3.26	6.68
15 hours....	5.00	5.66	5.54	5.4	4.11	.46
24 hours....	7.70	1.85	7.00	2.54	0.56	1.5
48 hours....	8.85	1.20	7.54	1.70	7.02	1.2
64 hours....	9.53	1.00	8.68	1.80	8.00	1.3
5 days.....	12.43	1.00	11.44	1.80	10.05	1.7
5½ days.....	12.68	.97		1.27		1.3
7 days.....	14.37	.50	14.00	.60	13.05	.26
9 days.....	15.21	.34	15.10	.50	14.18	.25
12 days.....	17.35	.82	18.32	1.21	17.40	1.2
14 days.....	17.83	.71	19.70	1.34	18.79	1.0
15 days.....	18.57	.60		1.01		1.2
18 days.....	19.76	.32	20.33	.43		.27

The differences are for periods of 24 hours each. We see that although the total amounts absorbed by these grains differ slightly, yet they seem to follow the same general law, i. e., a gradual increase, at first very rapid and then slowly becoming less until about the 13th or 14th day, when a sudden increase occurs. This is due to the development of mold owing to the great amount of moisture present. Nearly half the total increase occurs in the first 24 hours, and most of it in the first part of this time, as shown below. Difference between grains during the first 24 hours:

	8 hours.	15 hours.	24 hours.	14 days.
Oats.....	3.80	1.20	2.79	10.1
Barley.....	3.52	2.02	1.46	12.7
Wheat.....	3.26	.84	2.45	14.23

In the second 24 hours scarcely anything was absorbed. This was probably due to a sudden change of temperature.

Experiments were also made to determine the amount of water in the air-dry grains. They were exposed to a perfectly dry atmosphere at 18°. The apparatus employed was a common sulphuric acid desiccator. The grains, especially the wheat, shrank very much and became hard and bony. The results were as follows. The table of differences as before referred to periods of 24 hours: Percentage of water lost by air-dry grain exposed to absolutely dry atmosphere at 18° C.:

	Oats.	Differences.	Barley.	Differences.	Wheat.	Differences.
2 d'ys.4.45	3.00	3.39	2.00	3.11	2.00	
3 d'ys.5.67	1.45	4.41	1.30	4.13	1.11	
4 d'ys.6.53	.86	5.20	.81	4.63	.35	
5 d'ys.6.05	.48	5.51	.35	4.98	.11	
6 d'ys.7.43	.36	5.86	.24	5.00	.07	
7 d'ys.7.99	.19	6.14	.20	5.11	.28	
9 d'ys.7.14	.13	6.55	.10	5.13	.20	
11 d'ys.8.53	.12	6.96	.12	5.46	.18	
12 d'ys.8.60	.11	7.13	.10	5.51	.14	
18 d'ys.9.32	.09	7.79	.09	6.23	.01	

There is a gradual decrease, more rapid at first, as seen by the column of differences. About half is lost in the first two days.

According to the above determination, perfectly dry grain, exposed to a saturated atmosphere, will absorb the following amounts, at a temperature of 18° C.:

Oats.....	29.08%
Barley.....	23.17%
Wheat.....	25.02%

Wheat is thus seen to be less hygroscopic than oats or barley. Perhaps this is owing to the chaff of the latter.

As the temperature of the interior of the State in summer is about 80° F., the experiment of drying the wheat at this temperature was tried. The grain was placed in a flask, which was kept at a temperature of 30° C., by means

of a water bath, and dry air passed over. The results were as follows:

Temperature.	Time of exposure.	Percent. lost.
18° C.....	18 days=432 hrs.	6.23
30° C.....	30 hrs.	7.65

This shows that an increase of temperature increases the amount of moisture lost and decreases the time. According to Knop, wheat, dried at 120°, loses 14.6% of water.

The air even in the interior is never fully saturated. According to Logan the average dew point of the Sacramento valley in summer is 50, the temperature being about 70° F. This shows that the air contains 39.39% of moisture. The annual average dew point is 43, the temperature being 61° F. This corresponds to 52% of moisture. Experiments were made with air of this degree of saturation. This was done by means of a solution of chloride of calcium. According to Gay Lussac the tension of aqueous vapor formed by a solution of chloride of calcium of the specific gravity 1.343 at 10° C., has a tension of 50.5, the tension of aqueous vapor in a saturated atmosphere being taken at 100. In other words the air above each solution is half saturated. Since a solution at 180° (the temperature used) is less dense than at 10°, a correction must be made. It was assumed to decrease in the same ratio as water, and, therefore, a solution of specific gravity 1.3418 was employed. Wheat was placed over this and surrounded by filter paper as before. The amount absorbed by wheat dried at 30° C., from a saturated atmosphere and from a half saturated one, is shown below.

Amount absorbed in 12 days, temperature + 18° C.:	
Above solution of Chloride of Calcium.....	3.40%
"Water....."	22.9%

This result shows that half saturated air acts almost like dried air, and, therefore, that wheat from the Sacramento valley may be considered as being almost absolutely dry, and hence capable of taking up 20% or more of moisture.

We can now see what an important factor this absorption of moisture is in the case of grains. The great bulk of our wheat may be considered as dry during the summer, and on transportation to a damper climate may possibly increase 25%, and a gain of 5% to 15% may be looked for with almost absolute certainty. This is clear profit, and might just as well be appropriated by our farmers as by the commission merchants or foreign dealers.

Further experiments are necessary to determine the amount of moisture in newly threshed grain, and the rapidity with which it is lost when stored in the field and warehouses during summer; the effect of one-quarter, three-quarters or other intermediate degrees of saturation; the influence of large and small piles; and whether the difference of absorption of different grains is not due to the chaff. The determination of these points and also the degree of saturation of the air of the warehouses of San Francisco and large grain regions, will enable us to estimate the amount of moisture absorbed by the cereal grains very accurately.

The Age of Wonders.

A recent English writer, reviewing the scientific and industrial achievements of the past half century, calls this "the age of wonders," and refers as follows to a few out of the many modern marvels that fully justify the appellation:

We have seen a substance which our ancestors proudly used to obliterate a pencil mark so molded to our use as to make man almost an amphibious animal; a noxious vapor, from which they would turn with disgust, made the means of a brilliant light, which enables the night almost to rival the day. We have seen the surgeon's knife, to them an instrument of necessary torture, divested of its horror by a discovery which gives a temporary insensibility to pain, which enables the suffering patient to wake from nothing more than a troubled dream, and find that over, under which, without this, his fortitude might have faltered, or his constitution sunk. We have seen a power which is inexhaustible so long as the elements of fire and water remain, the effects of which our grandmothers may have witnessed with a sigh, when terminating, by a sudden crash, the serene music of their tea-kettles; but which, by the combined efforts of modern science, has become the very hands and feet of the world, the great and almost universal manufacturer for man; the great propeller by which we rival the flight of the bird, and which so unites the human family that degrees of latitude and longitude are little more than milestones on the great highway of the world. And, lastly, we have seen that subtle power which our ancestors recognized only in the minute spark of the electric circle transformed into the faithful, untiring agent of the human mind, bearing its thoughts from one end of a vast continent to the other with an accuracy which would be in vain looked for in any other messenger, and with a speed which far outstrips the action of the mind which formed them. "Quick as thought" will not do now to express the greatest speed, and "quick as lightning" has become a practical, not merely a figurative expression.

From March 8th to July 7th, \$25,231 in gold was received from a private gravel claim at Iowa Hill, Placer county. This claim is owned and worked by a retired merchant of San Francisco, and is only a single illustration of what a little capital, judiciously invested in gravel claims, will accomplish.

San Luis Park, Colorado.

From Gov. Gilpin's article in the *Colorado Miner* we learn that the San Luis park is an immense elliptical bowl, the bed of a primeval sea which has been drained; its bottom, smooth as a water surface and concave, is 9,400 square miles in area. It is watered by 35 mountain streams, which, descending from the encircling crest of snow, converge, 19 into the San Luis lake, the rest into the Rio del Norte. An extraordinary symmetry of configuration is its prominent feature. The scenery, everywhere sublime, has the ever-changing variety of the kaleidoscope. Entirely around the edge of the plain, and closing the junction of the plain with the mountain's foot, runs a smooth glasis, exactly resembling the sea beach, which accompanies the conjunction of the land with the ocean. From this beach rise continuously all around the horizon the great mountains, elevating their heads above the line of perpetual snow. On the eastern side the escarpment of the Cordilleras rises rapidly, and is abrupt; on the western side the crest of the Sierra Mimbres is more remote, having the interval filled with ridges, lessening in altitude as they descend to the plain of the park.

This continuous shelving flank of the Sierras completing a perfect amphitheater, has a superficial area equal to that of the plain which it envelops, and gives to the whole enclosure within the encircling band of snow an area of 18,000 square miles. At an elevation of 5,000 or 6,000 feet above the plain a level line upon the mountain wall marks the cessation of arborescence, and above which naked granite and snow alone are seen. To one who ascends to this elevation from any point, the whole interior of this prodigious amphitheater, displaying an elliptical arc of 11,520,000 acres, is scanned by the eye and swept in at a single glance. Aided by a glass, the smallest objects scattered over the immense elliptical area beneath are discernible through the limpid, brilliant and translucent atmosphere. Two facts impress themselves upon the senses; the perfect symmetry of configuration in nature, and the intense variety in the form and splendor of the landscape.

The average elevation of the plain above the sea level is 6,400 feet. The highest peaks have an altitude of 16,000 feet above the sea. In the serrated rim of the park, as seen from the plain projected against the canopy, are discernible 17 peaks, at very equal distances from one another. Each one differs from all the rest in some peculiarity of shape and position.

The park is an immense elliptical basin enveloping the sources of the Rio del Norte. It is isolated in the heart of the continent, 1,200 miles from any sea. It is mortised, as it were, in the midst of the vast mountain bulk, where, rising gradually from the oceans, the highest altitude and amplitude of the continent is attained. This park spreads its plain from 36° to 38° 30', and is bisected by the 106th meridian. Its greatest length is 210 miles; its greatest width is 100 miles; its aggregate approximate area is 10,000 square miles.

The comb of the Sierra, surrounding this immense bowl, presents the prodigious plates of primeval porphyry driven up, as the subsoil of a furrow, from the lowest terrestrial crust and protruding their vertical edges toward the sky.

The summit, yielding to the corroding forces, presents a wedge towards the canopy, is arranged in peaks resembling the teeth of a saw, is above all arborescence, and is either clad in perpetual snow or is bald rock.

Against this is lapped perpendicularly the second stratum, less by many thousand feet in altitude, its top forming a rim or bench. This bench, being the rended ridge of the erupted stratum, softer than the first and receiving the debris from above, has a deep fertile soil, a luxuriant alpine vegetation, forests of fir, and is the highest region of arborescence and vegetable growth.

This is the region of rocks, where the metals, especially gold and silver, abound in crevices charged and infused with the richest ores. It is from hence that the gold of the gulches is disintegrated and descends. Here are springs of water and the sources of rivers. The timber is excellent, and the pastures of various grasses luxuriant and inexhaustible. Swept by the ascending currents of vapor, irrigation is constant. This elevated bench is a permanent characteristic of the mountain flank, continuous as the continent itself; a colossal staircase, whose steps are themselves of mountain magnitude.

The enveloping Sierras, which hoop in the park in an unbroken circuit, have 1,000 miles of length. The cloud compelling crests, throughout and continuously, reaches and ascends into the region of perpetual snow. The veins of gold and silver-bearing rocks average all along 10,500 feet in altitude. They have a like continuous and undeviating length and circuit.

These veins are crossed and scored by 100 and more considerable streams, descending through them from the snows above. These all concentrate into the bowl of the park beneath. The channels, their confluent waters, and the sands from the full-veined mountains flanks, are here stopped and accumulate. The abrasions, going on during countless centuries, are here concentrated; they are gathered and remain upon the bedrock underlying the abraded debris.

The profound and subtle scrutiny given by Humboldt to the South American Andes is systematized in volume V. of *Cosmos* under the definition: "The reaction of the interior of the

earth upon its crust." He defines and often reiterates certain facts of generalization in their structure and contents. These illuminate and economize the intensely active fever now agitating our people in their search for the precious metals, and other precious contents of our North American Andes.

Two Cordilleras, imperfectly parallel, traverse South America from Cape Horn to Darien. These Cordilleras, are, comparatively, in quite close proximity. They seem at long intervals to cross, to intermingling their peaks, and to become mixed together. They are, nevertheless, distinct throughout. They contain between them a plateau depressed below the snow line. This is in Peru defined as the Puna.

Similar to our Northern Andes, the Eastern Cordillera, is the continuous crest that divides the drainage into the Atlantic ocean and into the Pacific ocean.

A special and peculiar characteristic of this dividing Cordillera, everywhere thus identifying it from all other mountain chains, is outflanking and parallel walls of trap dykes. These trap dykes issue from a depth more profound than the material of the Cordillera held between them. They are scrupulously parallel to one another, and are from 30 to 50 miles asunder.

The tops of the trap walls protrude through at an elevation of 10,500 feet above the sea. It is at this altitude, and packed against the four faces of the flanking trap walls, that the precious ores of gold and silver (chlorides and carbonates) are found to rest in nature as wall paper used in the parlors of ordinary dwellings. This is the altitude and outcrop of the mines of Copiapo in Chile, of Potosi in Bolivia, of Cerro Pasco in Peru, of El Doctor in Ecuador, and at Pachuca. All of these mines approach an uniform altitude of 10,500 feet.

The same law holds throughout the North American Andes from Darien to Behring's straits. The Cordillera is longitudinal in direction; uniform in structure, in rocks and in contents throughout its whole length of 12,000 miles from Cape Horn to Behring's straits.

It is from the above enumerated mines of the Southern Andes that the whole world has obtained its chief supply of silver for the past three centuries. This enormous production is now shifted into, and has its activity along, our counterpart North American Andes and within the territory of the American people.

The Sierra Mimbres, forming the western envelope of the park, is not dissimilar to the Cordillera in its origin, composition or configuration. Rising from the level of the great plateau, it is of inferior bulk and rank. It forms the backbone from whose contrasted flanks descend the waters of the Rio del Norte on the east and the Rio Colorado on the west.

Craters of extinct volcanoes are numerous; streams of lava, once liquid, abound; pedigrals of semi-crystalline basalt submerge and cover the valleys, into which they have flowed and over which they have hardened.

This Sierra, then, has a general deflection from north to south, corresponding with the 109th meridian. It has all the characteristics in miniature of the Cordillera, but is chequered and interrupted by the escape of subterranean fires, having areas overflowed and hurried beneath the erupted current. Where the nascent springs of the Rio del Norte have their birth, the Sierra Mimbres culminates to stupendous peaks of perennial snow, locally named Sierra San Juan.

The middle region of the plain, longitudinally, displays a crater of the most perfect form. The interior pit has a diameter of 20 miles, from the center of which is seen the circumference wall forming an exact circle, and in height 500 feet. This wall is a barranca, composed of lava, pumice, calcined lime, metamorphosed sandstone, vitrified rocks and obsidian. This circumference barranca is perforated through by the entrance and departure of the Rio del Norte, the Culebra and the Costilla rivers, which traverse the northern, western and southern edges of the interior. By this and other forces of corrosion this barranca is, on three sides, cut into isolated hills, called cerros, of every fantastic form and of extraordinary beauty of shape and tints. The bottom of the crater has been filled with the soils resulting from the decay of this variety of material, introduced by the currents of the water and of the atmosphere. It is beveled by these forces to a perfect level, is of the fattest fertility, and drained through the porous formation which underlies it.

From this crater to its southern rim, a distance of 65 miles, the park expands over a prodigious pedigral, formed from it in the period of volcanic activity. The pedigral retains its level and is perforated by the Rio del Norte, whose longitudinal course is confined in a profound chasm or canyon of perpendicular walls of lava, increasing to the depth of 1,200 feet, where it debouches from the jaws of this gigantic field of lava, near the village of La Joya, in New Mexico. Such are the extraordinary forms and stupendous dimensions with which nature here salutes the eye and astonishes the imagination. The expansion of the lava is all to the south, following the descent toward the sea. Toward the north, repelled by the ascent, are waves demonstrating the defeated effort to climb the mountain base.

The Nevada Herald says: The Live Yankee mine, near the Thomas, is to be another prominent institution from present appearances. At a depth of 125 feet the ledge has increased until it is about five feet thick, and miners, who ought to know, think the rock will pay from \$40 to \$50 per ton.

USEFUL INFORMATION.

POISON FOR RATS AND MICE.—Carbonate of baryta has been found to be a most efficient poison for rats and similar vermin. Indeed, at a special series of trials by the Zootechnical Institute, in connection with the Royal Agricultural College, at Proskaw, this substance was found to be more efficacious than any other. It occurs as a heavy white powder, devoid of taste or smell. In the Proskaw experiments it was mixed with four times its weight of barley meal, and pellets of the paste were introduced into the holes of the rats, house mice, and field mice. A small quantity proves fatal. It appears to cause immediate and complete paralysis of the hind extremities, so that it may be assumed that mice eating of it in their holes will die within them, and so not prove destructive in their turn to domesticated animals that might otherwise devour the carcasses. It was found in practice that neither fowls nor pigeons would touch the paste, either in its soft state or when hardened by the sun; so that its employment is probably free from danger to the occupants of the poultry yards. Some rabbits, on the other hand, that got access to the paste ate heartily of it and paid the penalty with their lives. Next to the carbonate of baryta paste, the ordinary phosphorus paste proved most destructive, and this, it was found by experiment, is more attractive to the mice in a soft form than when hardened into pills. But it is considerably dearer than the baryta preparation, an important factor in the calculations of the farmer who has to wage war against rodents on an extensive scale.

GLUE.—Carpenters should remember that fresh glue dries much more readily than that which has been once or twice melted. Dry glue steeped in cold water absorbs different quantities of water according to the quality of the glue, while the proportion of the water so absorbed may be used as a test of the quality of the glue. From careful experiments with dry glue immersed for 24 hours in water at 60° Fah., and thereby transformed into a jelly, it was found that the finest ordinary glue, or that made from white bones, absorbs 12 times its weight of water in 24 hours; from dark bones, the glue absorbs 9 times its weight of water; while the ordinary glue, made from animal refuse, absorbs but 3 to 5 times its weight of water.—*Building News.*

FORMATION OF COAL.—E. Frey holds that there are several kinds of isomeric cellulose, constituting the skeleton of plants. Coal is not an organized substance. The vegetal impressions presented by coal are produced as in shales or other mineral matters. The chief substances contained in the cells of plants under the double influence of heat and pressure produce bodies having a great analogy to coal. The pigments, the resins, and the fats of leaves, if submitted to heat and pressure, yield compounds which approximate to bitumens. The vegetable matter which gave rise to coal has undergone, first, the peaty fermentation, the coal being then formed by a secondary transformation.

FLUORESCENCE.—J. L. Soret has already pointed out the beautiful violet fluorescence of solutions of cerium sulphate and chloride elicited only by the extreme ultra-violet rays of the induction spark, the solar rays not being sufficiently refrangible for its production. He has since found that the solutions of many salts of the earthy metals possess analogous properties. He enumerates lanthanum chloride, didymium chloride and sulphate; terbium, yttrium, erbium, ytterbium chlorides; plibbium chloride; thorium sulphate; zirconium sulphate and chloride; aluminum and glucinium chlorides.

STRAIN ON PIANOS.—The strain on 7½ octave large concert grand Steinway & Son's piano is 66,000 pounds. Parlor grands of the same make average 30,000 pounds strain each; and upright pianos, having also three strings to each note, from 20,000 to 25,000 pounds, according to size; the square grand pianos, 7½ octave, being partly three-stringed to each note, about 20,000 pounds; 7 octave square pianos, two strings to each note, about 16,000 pounds each.

BRASS CASTING FROM OLD METAL.—A white scum of oxide sometimes forms very rapidly, and going into the molds with the metal makes the castings porous and rotten, especially is this the case when old metal is used. To prevent, stir the molten metal well with a stick of green wood, and sprinkle with a little dry argol and sal ammoniac before pouring.

SOLID EMERY WHEELS.—Many of the best wheels are cemented with vulcanized rubber, borax or zinc chloride (or oxychloride) and barium carbonate; other materials, such as feldspar and clay, alkaline silicates, litharge and japan, shellac, and other resinous and gummy matters, albumen and lime, etc.

TARTAR EMETIC IN DYEING.—Dr. Reimann advises those engaged in cotton dyeing to discontinue the use of tartar emetic. It does not fix the aniline colors themselves, but merely fastens the tannin, and as antimony can be dispensed with there is no reason why health should be endangered.

TO INSULATE WIRE.—Shellac varnish makes a good insulator for wire, provided the wire is wound before the varnish becomes thoroughly dry.

TO PRESERVE NATURAL LEAVES.—The fresh leaves are spread and pressed into a suitable dish with alternate layers of fine, thoroughly dry sand, as hot as the hand can bear. When the sand has cooled they may be removed, smoothed, and dipped for a few moments in clear French spirit varnish, and allowed to dry in the air. By many melted white wax is preferred to varnish. This latter must not be too hot. The dried leaves are dipped in the melted wax, drawn several times over the edge of the vessel to remove excess, and hung up until the film of wax is thoroughly cooled and hardened.

PROTECTING VULCANIZED RUBBER.—To protect vulcanized rubber against the action of oils and fats, Herr C. Schwanitz, Jr., of Berlin, works in the rubber by rolling through heated rollers a mixture of 6 pounds of prepared chalk, 3.2 ounces of sulphur, 1.67 ounces of litharge and 1 pound of glycerine of 1.23 specific gravity. In order to vulcanize articles made and shaped from this material, they are placed in a bath of glycerine, and all exposed to a pressure of steam of two to three atmospheres.

GUTTA-PERCHA SOLVENTS.—Caoutchouc and gutta-percha are both quite soluble in naphtha, benzole and carbon disulphide. The latter, when mixed with about 6% of absolute alcohol, is one of the best solvents. The solution is performed in the cold (best in the open air), as it would not be safe or economical to heat these volatile and inflammable liquids. Exposed to the air the solutions soon evaporate, leaving the gums in their original condition.

INDELIBLE INK.—The *Apotheker Zeitung* gives the following formula: 1.75 grammes aniline black are ground up with 60 drops hydrochloric acid and 42 grammes alcohol, and the liquid is diluted with a hot solution of 2.5 grammes gum arabic in 170 grammes water. If the aniline black solution is diluted with a solution of 2.5 grammes shellac in 170 grammes spirit instead of gum water, the result is an ink suitable for writing on wood, brass or leather.

DYED COCOONS.—A Spanish silk spinner has hit upon the ingenious idea of adding dyes to the warm water which is used for detaching the silk fibers from the cocoon, and thus to dye the fiber as it is being formed into thread. His object is to obtain a dyed thread which is to contain all the natural gum and luster, and which, on that account, will retain the color more easily and readily.

LIME WATER.—Agitate an ounce of pure caustic lime in a pint bottle nearly filled with water, and after the lime has subsided decant the clear supernatant liquid. It must be kept in well stoppered bottles.

GOLD IN PETROLEUM.—According to the *Bergmann*, Mr. J. Turnbridge has extracted \$34 worth of gold from a ton of the residues from petroleum stills. The source of the petroleum was not ascertained.

GOOD HEALTH.

Epidemics.

The limitation of epidemic pestilential diseases, as the yellow fever, typhus and typhoid, diphtheria, etc., is at all times a question of intense interest to every thoughtful person. The July number of the *New York Sanitarian* contains interesting and valuable matter upon the subject of epidemics, which we unhesitatingly appropriate.

The cholera is a product of the jungles of India and Burmah, and the yellow fever is as surely of West Indian origin. That it is an exotic as relates to the United States is the opinion of the last national commission; and that it never originates *de novo*, except in its primal birth-place, whatever elsewhere may be the excess of heat moisture, filth, and vegetable and animal decomposition, is almost demonstrated, perhaps established. As to communicability, it is certainly conveyed from individual to individual, not precisely by what we understand to be direct contagion, but through various media, especially by bed and body clothing, by articles of furniture, by apartments, cars and steam and sailing vessels, by baggage and by cargoes; and these propagators, deriving from the sick the pestilential material (intentionally not called germ), hold it with wonderful tenacity, and convey it to mankind with intense effect. Both may be held at bay by quarantine and literally "fenced out." In 1851 cholera prevailed in Southern Europe and in Algeria, but not one case occurred that year in Spain by reason of vigorous quarantine. Two years later, when the embargo was not strictly maintained, it ravaged the Spanish peninsula. It always followed the lines of travel and was always carried by mankind. The infectious germ might be traced in germinating, but it could always be traced to individuals. Quarantine, to be effectual, however, must have a very wide applicability. It will not suffice to limit it to vessels from foreign ports. It must extend to all conveyances for the transportation of passengers and merchandise—must have relations with municipal, State and national authority. It is estimated that the cost of the late yellow fever epidemic in loss amounted to \$200,000,000.

Typhoid fever is certainly communicated

through a tainted water supply exposed to the taint of infected vaults. Poisoned springs have been traced to this infection, and in a celebrated English dairy case, where poisoned milk was claimed to have been sold, scientific examination disclosed the fact that the milk had been contaminated through the cows having lain upon ground manured from infected vaults. Another source is in the ice supply, often taken from shallow ponds in the neighborhood of large cities, freezing not destroying the germ as supposed. The air in localities becomes contaminated from sewage deposits; and Budd states, as early as 1859, that the germ of this disease never originates *de novo*, but proceeds from a special and specific poison, capable of great diffusion and preserving its noxious qualities for a long period, even if buried for many months. In England the preventability of typhoid fever is so thoroughly established that an innkeeper who has a guest ill with it, is held criminally responsible if any other case could be traced to the one under his roof. By this means infectious substances are destroyed and the spread of the disease prevented. Boiling water applied to the discharges is said to destroy the infection. But when the substance is allowed to escape as sewage it must be disinfected by prompt means.

Diphtheria is much more prevalent and much worse in localities supplied with bad water. The microscope can detect a few of the germs of epidemic diseases either in the water or in the system, and the only sure method is to watch the slightest approaches of disease and investigate the sources of our water supply, whether in city or country. Chlorine gas, from recent experiments, seems to be a disinfectant as well as a deodorizer. This greenish-colored gas effectually seizes upon and destroys any hidden germs existing in dwellings, ships, etc. This gas has been used successfully at Bellevue hospital and other places. We must purify and quarantine. Mediums of communication have been made available to epidemics as well as to mankind in his business affairs.

WRITER'S CRAMP.—Dr. George M. Beard, in a paper on "Writer's Cramp," published in a recent number of the *Medical Record*, concludes, from a study of 125 cases, that "this disease occurs mostly in those who are of strong—frequently of very strong—constitutions, and is quite rare in the nervous and delicate; and when it does occur in those who are nervous, is easier relieved and cured than when it occurs in the strong." That it "is far less likely to occur in those who do original work, as authors, journalists, composers, than in those who do routine work, as clerks, book-keepers, copyists, agents, etc. Like all nervous diseases in this country, it diminishes in frequency as we go South." It is no longer an incurable disease, electricity and massage being the best remedies. Hygienic measures consist of ring penholders, so as to relieve the thumb and fingers; large penholders, or fastening a piece of sponge to the penholder, so that the muscles may be less restricted; changing the hold of the pen between different fingers; the use of quill or other flexible pens, or pens with broad points, which run easily, like quill pens, and taking pains to avoid too long confinement in one position.

PRESENCE OF MIND.—Prof. Wilder gives these short rules for action in cases of accident: For dust in the eyes, avoid rubbing; dash water into them. Remove cinders, etc., with the round point of a lead pencil. Remove insects from the ear by tepid water; never put a hard instrument into the ear. If an artery is cut, compress above the wound; if a vein is cut, compress below. If choked, get upon all fours and cough. For light burns, dip the parts in cold water; if the skin is destroyed, cover with varnish. Smother a fire with blankets, etc.; water will often spread burning oil and increase the danger. Before passing through smoke take a full breath, and then stoop low, but if carbon is suspected, walk erect. Suck poison wounds, unless your mouth is sore; enlarge the wound, or, better still, cut out the wound without delay, holding the wounded part as long as can be borne to a hot coal, or end of a cigar. In case of poisoning, excite vomiting by tickling the throat or by water and mustard. In case of opium poison, give strong coffee and keep moving. If in water, float on the back, with the mouth and nose projecting. For apoplexy, raise the head and body; for fainting, lay the person flat.

THE FLUIDS OF THE BODY.—Prof. Jager, of Leipzig, has recently published a work in which he maintains that an increased proportion of water in the tissues and humors of the body is one of the most essential conditions of liability to disease. To guard against disease, therefore, it is necessary to make the body yield as much water as possible through skin and lungs, and to avoid all that favors the accumulation of water. To this end he recommends the wearing of close-fitting woolen clothing throughout the year; all bodily movements which promote perspiration; on outbreak of disease the use of vapor or sweating baths, of drinks that excite perspiration, and of foods that do the same; constant ventilation of sitting and bed rooms, so that the moisture of the air may not become great. Dr. Jager asserts that the specific gravity of a living body is an accurate criterion of the strength of constitution of a man or a domestic animal—that is to say, for its capability of resistance to causes of diseases, such as chills, infection, etc., and its power of work, bodily and mental.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Mineral Veins—No. 1, 49. The Week; Over-Exacting; A Half a Century of Railroads; Mining in Trinity County; Bullion, 56. The Mineral District of San Salvador; A Spring Horse Shoe; The Iron Mine Case, 57. Notices of Recent Patents, 60.

ILLUSTRATIONS.—Theory of Mineral Veins, 49. Mineral Section of San Salvador; Yates' Horse Shoe, 57.

CORRESPONDENCE.—Developments on Silver Hill, Bodie; Mines and Mining in Tuolumne County, 50.

MECHANICAL PROGRESS.—Transmission of Power by Shafting; Communications with Lighthouses; A Very Simple Pantograph; Boiler's Steam Carriages; Recording Thermograph; Preparing Carbons for the Electric Light; Wind Gauge; A Voltaic Pencil; Electric Inscription of Words; A Knowing Engine, 51.

SCIENTIFIC PROGRESS.—Photography on Wood; The Telephone as a Lightning Indicator; Improvement in Sugar Manufacture; The Robertson Process; Magnets in the Mills; Preservative Wrapping and Packing Paper; Lightning Rods; The Mont Ventoux Meteorological Observatory, 51.

MINING STOCK MARKET.—Sales of the San Francisco, California, and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 52.

USEFUL INFORMATION.—Poison for Rats and Mice; Glue; Formation of Coal; Fluorescence; Strain on Pianos; Brass Casting from Old Metal; Solid Emery Wheels; Tartar Emetic in Dyeing; To Insulate Wire; To Preserve Natural Leaves; Preserving Vulcanized Rubber; Gutta-Percha Solvents; Indelible Ink, 55.

GOOD HEALTH.—Epidemics; Writer's Cramp; Presence of Mind; The Fluids of the Body, 55.

MISCELLANEOUS.—Recent Patent Decision; New Spectrometer; Microphonic Study; Comparative Strength of Wood and Iron, 50. The Absorption of Hygroscopic Moisture by Cereal Grains; The Age of Wonders; San Luis Park, Colorado, 54-55.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon and Washington Ter., 51-60.

NEWS IN BRIEF on page 90 and other pages.

Business Announcements.

Delinquent Sale—Numa Mining Co., David Wilder, Sec'y. Mechanics' Fair, J. H. Culver, Secretary, S. F. Yosemite and the Geysers, Matteson & Harrison, S. F. Bodie Stage Line, Matteson & Harrison, S. F.

The Week.

Our weekly chronicles are without events calling for special notice. The mining interests of the coast are, as a whole, being well prospered. The Comstock mines are making less bullion than could be wished, but elsewhere the production is being well sustained. With the hydraulic miners of California, the water season, after being prolonged beyond expectation, is in most localities drawing toward a close. Cleanups, now in order, promise to be satisfactory, and in some cases unusually large. The mining prospects of Alpine county, for many years obscured by reverses, are reported as having undergone marked improvement of late, considerable Eastern capital having come to their aid and some very encouraging ore developments having been made. The Robertson process, without having yet achieved anything determinate of its value, seems to have gained favor in some localities, where it has treated small lots of ore with apparent success. We await the results of larger workings and more crucial tests. The managers of the large mines at Eureka, Nevada, threaten, in the event of their being unable to obtain charcoal on satisfactory terms, to send their ores to California for reduction, a procedure which, while it might prove economical to them, would prove a great detriment to the town and wholly ruin the charcoal burners, who would be left without a market for their coal. After all the talk about the people of the East growing emotional over our mines, they seem to be taking matters coolly, their investments being made with caution and their enthusiasm being of a very subdued kind. It is hoped that when the torrid season is over they will warm up to the business, and evincing a more lively appreciation of the many opportunities offering for investment, lose no time in improving the same.

It is reported that Madam Elizabeth Patterson-Bonaparte is to have a \$4,000-tomb at Greenwood cemetery.

Over-Exacting.

From the reports of parties lately returned from the Atlantic slope we judge there is in the larger towns there no lack of adventurers from the various mineral districts of the far West, all bound on errands connected with the sale of mines, the raising of capital for working purposes and similar objects. While this class has representatives in all the considerable towns and places of popular resort, the most of this army of vendors, negotiators and promoters make their headquarters in the city of New York, as being the most active center of business and capital. Contrary to the general impression it would appear that the schemes and properties so being presented for the consideration of Eastern investors, though very numerous, are hardly ever wholly devoid of merit. So much have the people abroad suffered through hasty and ill-advised mining investments on this coast that they have become exceedingly chary in their purchases, refusing to touch anything until doubly assured that it is in all respects legitimate and safe. To float there anything absolutely worthless is now impossible. A mining property will not even be noticed without something to recommend it in the first instance, and before any money will be put into it, it must, in the absence of a satisfactory public record, receive the endorsement of a competent mining expert, based on a personal examination recently made. Such approval, by even more than a single expert, is sometimes required, and that where the mine may have a good history to back it. Under these rigorous requirements it will be seen that the chances for disposing of a worthless or even a decidedly poor mine in the East are slim indeed.

In fact, we do not know but our Eastern neighbors are becoming a little more exacting in this respect than we on the Pacific coast. It is our custom to accept the report of one or two competent authorities on the character of a mining property, whether favorable or otherwise, as conclusive; not so the people or rather the press on the other side. The *Record*, published in New York, quoting an article from the *Fair Play Flume* on the over capitalization of the Little Pittsburg mine, condemns by implication such arrangement as not warranted by the prospective resources of the property, which, nevertheless, stands approved by such men as Rossiter W. Raymond, and other great lights of the profession. So, in like manner, that journal, taking for text something in disparagement of the Carrie Steel mine that appeared in a Silver Reef paper, proceeds to comment unfavorably upon that property, which, besides a good record reaching back through a number of years, was not long since bought on the recommendation of Prof. Clayton and other competent judges who had carefully examined it. It is true, the *Record*, finding that its criticism was uncalled for, hastened to correct the same in its next issue, yet the disposition on the part of these New York papers to guard the interests of their constituency from even the semblance of harm is noticeable. Nor do we complain of this vigilance, since, although not always required, but little evil can come from its over-exercise.

It may, however, be pertinent to remark in this connection that when Eastern investors have availed themselves of the services of such men as Raymond and Clayton, they have done about all they can do to obtain intelligent and reliable information in regard to this class of properties, and they may as well, as is the habit with us, conclude to accept their reports as final, disregarding thereafter all rumors and remarks, *pro* or *con*, whether issuing from the local press or uttered by private individuals. The successful placing of a mine often awakens jealousies which are apt to find expression in ill-natured remarks, or there will be the unwarmed and those who, through failure to reap satisfactory benefits from the transaction, will seek to discredit it. It is said that some of these adventurers now in the East, when they learn of negotiations pending for the sale of a mine, are not above seeking to obstruct the same unless bought off, continuing often to malign the property after it has been disposed of; in view of which buyers should not be surprised if they sometimes hear their purchases illy spoken of.

Touching the Carrie Steel mine, we know it has always enjoyed a good local reputation, and believe that it has been more than self-sustaining from the first, the original owners having from its net earnings defrayed the cost of all developments and improvements made upon it, besides discharging a considerable amount in dividends. As to its present ore stock, whether extracted or held in reserves, whatever Prof. Clayton has reported the same may be safely accepted as the basis of any business transaction whatever. As a competent and conscientious mining expert he has no superior on the coast. Of the parties in this city who indirectly promoted the sale of this property in New York, we can also say their business standing is of the very best. Of their co-operators in New York we know less, but presume persons interested there have satisfied themselves of their trustworthy character. The principal promoter of the enterprise in New York is a banking house of excellent repute, and we understand that not less than three other institutions of a similar kind have been instrumental in securing the

stock of this company for their clients, nearly all the shares disposed of having gone into the hands of rich and influential parties. That these banking houses would not be likely to imperil their good name by accepting the agency of any questionable business may safely be assumed. That they would expose their credit to suffer in consideration of commissions to be paid them is out of the question. If our Eastern friends purpose to engage in the business of mining they must not hope to incur less risk than is involved in cases of the kind here alluded to; nor can investments under such guarantees be considered at all hazardous.

A Half Century of Railroads.

On the 27th of October next, it will be just 50 years since the first locomotive solved the problem of railroad transportation. Unbelievers were many, and one critic, a member of the English committee, inquired of Stephenson, the engineer, whether his machine, running at the rate of nine or twelve miles per hour, would not cause a terrible accident if it should meet an obstacle, a cow for instance. "Yes, to the cow," quietly replied Stephenson. The application of steam to highways was the dawn of a new era in freedom of communication and transportation. Since the introduction of steam as a motor, wonderful improvements have been made, and if it was difficult for contemporaneous witnesses to grasp the immensity of the discovery, it is no less difficult for us now, after 50 years of use, to fully measure all of the direct and indirect consequences that flow from this marvelous means of communication.

George Stephenson declared his discovery to an assemblage of English engineers on the 27th of October, 1825, and on the 17th of September, 1830, the first English railroad was opened between Liverpool and Manchester. Belgium speedily followed the example of England, and in 1837, France inaugurated the Paris and Saint Germain railroad. In 1835, five years after the first railroad, 1,320 miles of road were in operation in the world. At the present time, or at least at the commencement of the year 1878, for our general statistics stop at that year, Europe possessed 94,128 miles of railroad while the United States had about 30,000 miles, and all other parts of the world about 22,000 miles.

These figures are taken from a valuable German work which appeared in the *Gazette d'Augsbourg*. The author states that the capital employed in the building of the railroads of the world amounts to \$15,000,000,000, (60 milliards de marks.) An enormous capital for a single industry not yet much older than the average life of man. Here, continues the author, is a fact in political economy never seen since the world began. It has exercised a predominating influence over all human relations, sensible not only in the material domain, but in the intellectual and moral condition of civilized people. Journalism has notably become subject to this influence, since political wants and views, as well as social contiguity change in proportion as we have become cosmopolitan, or have increased our triumphs over the forces of nature in becoming independent of time and space.

Railroads have entirely changed the conditions of productions. They, with steamships, have enabled thinly settled localities of the world, to produce immense crops upon virgin soil, and compete with and triumph over the denser population but worn out soil of older Europe. If 50 years of steam communication have produced such an astonishing result, what may we not expect at the end of a second half-century?

Mining in Trinity County.

From Capt. Geo. H. Atkins, an experienced hydraulic miner and old resident of Trinity county, who called on us a few days since, we learn that the present is likely to prove a very good mining season in that section of country. Although the snowfall on the mountains was lighter last winter than usual, the water supply owing to an absence of any extremely hot spells of weather, has held out this summer better than was expected, most of the companies having still water enough to continue pining. The output of gold for the county will amount this year to a million and a half dollars, very nearly the yearly average of late. As the most of the mines here are held under many small proprietorships and the net profits realized are large, this production meets with wide distribution, almost the entire community participating in its benefits. There is not in the State a people better off, as regards physical comforts, than those of Trinity. If they have few millionaires they have at the same time but little destitution and no pauperism there; and what is a little singular in these latter days the pecuniary condition of the inhabitants is every year improving. This grows out of the fact that nearly everybody, as stated, is interested in the mines, and the additional fact that the mines pay with great steadiness and certainty. In no part of California is the income from this source better assured than in Trinity.

The facilities for carrying on hydraulic operations, the principal branch of mining here, are very superior, being hardly equaled elsewhere on the coast. They may not have as many deep-lying channels in Trinity as in Nevada

county, but the gravel, as a general thing, is richer and water more abundant and easily supplied, while in the matter of outlet this section of country is wholly unrivaled, such a thing as trouble from accumulation of tailings never having occurred, as indeed it never can occur except it be in the Weaver Basin or at one or two other points where only operations upon a limited scale are being conducted. All the large mines dump directly into Trinity river or into steep canyons that debouch into that stream, which latter with its powerful current sweeps away everything emptied into it. As yet not a pound of debris has ever made permanent lodgment in the bed of this river. Where a hydraulic claim discharges its tailings directly into the Trinity, a fall of 50 feet is just as good as a fall of 500, as the freshets that annually occur here carry everything clean away. Besides this advantage, the hydraulic deposits in this country are for the most part free from overlying volcanic or other barren matter, a difficulty with which the hydraulic miner further south often has to contend. These favorable conditions of the Trinity gold-bearing gravel banks have begun to attract notice, causing some investments on both California and Eastern account to be made there of late. It is the case, however, that the field for investment is not very extensive in Trinity, and promises soon to be filled in so far as it invites money from abroad. What openings exist here for outside capital are first-class, but they are rather limited. The small claims that can be worked to advantage without the aid of capital are numerous, and will remain in present hands.

Bullion.

The amount of bullion received at San Francisco during the month of May, 1879, from 59 mines was \$2,138,793, of which \$893,700 was gold, the rest silver. The total amount received from the same mines for the five months ending May 31st, was \$11,773,927, an average of \$2,354,785.40 per month. Of the total, Nevada must be credited with \$8,477,269 from 28 mines; Utah, \$638,400 from 4 mines; Arizona, \$342,189 from 3 mines, and Dakota, \$131,000 from 4 mines; leaving a balance of \$2,185,069 to the credit of California, the product of 20 mines. So far as known the bullion receipts for June amounted to \$816,589.40 from 29 mines. So far as the State of California is concerned the monthly yield of bullion from the mines all over the State averages \$1,700,000 gold and silver. There are numberless small mining claims which go to swell the total amount of bullion, and taking our local receipts and what is shipped through other channels, the annual product will not fall far short of \$18,000,000 for the past year for California alone.

The total export of bullion from the port of New York since the 1st of last January amounts to \$11,201,094 in gold and silver, silver predominating nearly 9 to 1—an excess over last year's exports of about \$3,000,000. The imports are very small in proportion to the total imports for the same time, hardly exceeding the exports of the past week. The figures of the official report of coinage at the San Francisco mint for the year ending June 30th, 1879, are as follows:

Double Eagles.....	\$27,680,000
Eagles.....	261,000
Half Eagles.....	834,500
Quarter Eagles.....	565,700
Total Gold.....	\$29,322,200
Standard Silver Dollars.....	12,725,000
Grand total.....	\$42,051,200

To make this coinage, the bullion supply was drawn almost exclusively from the Pacific coast mines, and excluding the silver, etc., from Utah, Colorado and Dakota, the most of which finds its way East in bars, as does also considerable of the silver product of Arizona, we can arrive at an estimate of the condition of the Pacific slope mines as bullion producers. Here gold predominates, as will be seen, over two to one. Most of the silver is exported, except what is needed for our own circulation, while the greater part of our gold is retained. The experimental solution of the silver problem in Germany, entailing a loss in the supply of that country amounting to about \$25,000,000, has created a desire to increase the amount of silver in circulation. Sales of silver have ceased in Germany, and the deficiency of \$25,000,000 must be made up. The astute statesman, Bismarck, was somewhat dismayed and puzzled to account for such an immense loss to the government through recoinage, and has undoubtedly influenced the suspension of sales until the exact amount on hand can be determined. The result of examination can only be a demand for silver which will be felt here in renewed energy to supply the market. China demands considerable silver, in fact out of \$367,913, shipped from this port to that country during the month of June last, only \$52,666 was gold coin and gold dust, and out of the total exports, viz., \$1,193,559, only \$126,786 was gold coin. China has a weakness for Mexican dollars, while Honolulu and Central America prefer gold coin and trade dollars.

EASTERN ARIZONA.—Paying placers have, it is reported, been discovered on the Francisco river, not far from Clifton. The Clifton copper mining company are going to have a railroad from their mines to Clifton.

The Mineral District of San Salvador.

[Written for the Press by G. K.]

San Salvador possesses many mineral ledges, principally silver and gold veins; also bituminous coal, sulphur, etc., but the most important mineral district is that of San Miguel, of which I send you a sketch. The climate, although warm, is nevertheless healthy, even in the rainy season, at which time the natives are principally the sufferers, having open miserable houses, of one or two rooms, or rather partitions, neither wind nor water-proof, and there is no wonder if a fellow, once sick, dies in consequence of exposure and misery. Sweating is permanent but wholesome. In the mining region it is somewhat cooler. The rainy season commences in the month of May, moderates the heat, and ends in October. The Salvadorians do not seem to take much interest as yet in mining, therefore, in this respect, the country is not developed. They cultivate coffee, indigo, rice, corn, etc., and leave the mining to foreigners. The living is not very cheap, unless one is satisfied with rice. The first-class hotel in La Union charges \$1.50 per day; the second, 75 cents; the difference is only in the meals, other accommodations are alike. The import duties are 70% even on flour and wheat, while the neighboring Honduras takes only 30% on flour, and will permit free import of this article from August next.

The people here are good-natured, and there is no necessity of having always a revolver hanging on his side while he is traveling, as is indispensable in Mexico, nor are the foreigners hated here like in Mexico.

Politics are quiet here, except the very diligent drilling of troops from six in the morning to ten, and for two hours more in the evening, Sunday excepted. It looks as if a war was impending. The drilling is going on in La Union, San Miguel, La Libertad, and Salvador, it is said for the reason that the election of the President is approaching, and the present President don't like the short term of his office.

The roads are good in the dry season; machinery can be forwarded on wagons to all mines from La Union. There are many abandoned mines worked to a very limited extent, some of which have been denounced lately; others, like Loma Larga, Tabanco, Enquentros, etc., are in operation for 15 to 25 years. The facilities for working are favorable. Salt costs at the mines \$27.50 per ton, wood \$2 to \$2.50 per cord, and native labor 50 to 75 cents per day. Several mills have water power. The principal pulverizing medium is the *arastra*. At present there are only two mills using batteries, one is Loma Larga. This mine is owned principally by Gen. Gonzales, residing in Nicaragua. The ore is excellent, contains native silver, silverglance, etc.; very little of base metals, yielding bullion over 900 fine from roasted ore. The mine is worked to a depth of about 150 feet, but considerably in the horizontal extent. There is a great deal of water in the mine, keeping two pumps at work, furnishing more water than is required for mill purposes. Since the discovery a great deal of silver must have been taken out of this mine, which I could not ascertain, but during 21 months last past \$173,000 worth of silver has been extracted, besides \$54,300 in exported ore that was shipped to England. This would seem a moderate production, but it must be taken in consideration that the ten stamps make not more than 50 to 60 drops per minute, with many interruptions, therefore doing no more work than one regular battery of five stamps. Then the improper amount of silver and gold left in the tailings and what goes through the chimney. There are four pans in the mill and two settlers; in these pans the ore was first amalgamated raw, but a better result was obtained after roasting. Although the ore contains gold, preference is given to barrel amalgamation, of which there are eight, because the barrels give a better result. The blame is wrongfully given to the pans, instead of to the so-called panman, who knows how to charge and discharge a pan, but not how to amalgamate. The roasting is done in two reverberatory furnaces, one has three hearths with flues several feet high between, the other has likewise three hearths, but nearly on same level. The roasting itself is not executed systematically, and neither the loss in roasting nor the percentage of chlorination is known, two facts on the proper knowledge of which alone a proper roasting can be based. A Dr. Gaertner tried to improve the manipulation by using sulphate of copper in pans on roasted ore, up to six pounds per charge of one ton. There is another mine, San Pedro, belonging to the same company, not far from Loma Larga, the ore of which is reduced at Loma Larga.

The other mill, having one battery with five stamps, is at Tocoero, a few miles east of Loma Larga. It is a gold-bearing ledge called the Flamingo; was lately denounced by Mr. Miller, and a substantial five-stamp mill with engine, two pans and a settler, procured from San Francisco, and started a few days ago. This concern belongs to Miller & Auerbach.

Tabanco is another important mining place, owned by a French company (credit mobilier). This company has spent a great deal of money in building excellent roads; dam, with a long, very substantial ditch, but only uses water-power, which ceases in the dry season. The pulverizing apparatus is an *arastra*, driven by a turbine. The pulp is then dried, sifted and

roasted with salt in reverberatory furnaces, and finally amalgamated in barrels, after the Freiberg pattern. This company has worked their mines in Tabanco for over 15 years.

Northwest of Tabanco is the reputed Monte Mayor mine, owned by Manning & Co., Liverpool, England. This company purchased Monte Mayor, with four or five other mines, twelvemonths ago, for \$245,000, and these mines are going to change owners now. There is a good water-power here, abundant wood and all facilities for successful working.

Corezal, southwest of Loma Larga, is a valuable mining property, belonging to Mr. Macay. Besides Corezal he owns the mines Barroz, Miguelito, Guarumal, Prodigioso, and Divisadero. The latter is near Loma Larga, but the ore is transported to Corezal. The Divisadero ore shows native silver and sulphurets and very rich specimens are taken from this mine. This Corezal mine is very wide, but carries a good deal of base metals, principally zincblende, besides copper pyrites, galena and antimony. The mill is very interesting on account of the machinery it contains. At present there is an *arastra* at work to grind the ore, driven by an engine of 12-horse-power, grinding from four to five tons per day (24 hours). The pulverized ore is discharged on the periphery through screens and deposited in a vat, wherefrom it is taken out, dried, sifted through a rotating cylindrical sieve, 64 meshes to the square inch, roasted in a reverberatory, and amalgamated by the patio process. At least so at present, but

A Spring Horse Shoe.

This progressive age suggests another valuable invention in the form of a steel spring horse shoe, that has been thoroughly tested on a number of valuable horses, having various shaped hoofs, in good as well as sore condition, and found to have had a very beneficial effect in every instance. Horses shod in general must be regarded as a necessary evil to enable the horse to perform his duty on the artificial, hard, stony roads and streets, and the art of successful horse shoeing consists in surmounting the obstacles nature has thrown in this way. Very little attention has, as a general thing, been paid to the peculiar growth of the hoof. The gradual transformation from the normal to the abnormal form caused through domestication and violation of the laws of nature, such as confinement in stables, lack of moisture in hoofs, owing to the dryness of climate and inattention, as well as wrongly calculated proportions of metal improperly distributed over the foot in the form of shoes, is the main cause of so many hoof evils, which ruin many horses.

The new spring heel shoe, herewith illustrated, was recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Mr. H. G. Yates of this city. Such is its peculiar construction that with every step it gives a yielding resistance, and arrests the vibration caused by jarring or pounding on hard roads, this

there is a Stetefeldt furnace that cost \$6,000, and gave, according to Macay, excellent results, although without a feeding apparatus, so that the ore had to be introduced irregularly. There are also six amalgamating barrels, this amalgamation of which was satisfactory in regard to silver, but only 10% of the gold was obtained. There are also three stamps, two in one battery and one in the other, prepared for wet crushing, a singular English construction, the stems being without tappets, short, and connected with a crank shaft. These three stamps should pulverize about 15 tons in 24 hours, and supply three jiggers of this best pattern made in England, and three eight-foot wide Rittinger percussion tables, also imported from England, all of iron and of excellent workmanship. Having all this machinery and a Stetefeldt furnace Mr. Macay prefers the more simple handling by an *arastra* and patio amalgamation. Of course a good battery is indispensable to keep the Stetefeldt furnace going and pans, or the lixiviation process likewise. Mr. Macay is willing to make an arrangement with some party profitable for both.

At Enquentros are several ledges, belonging to the same French company which owns Tabanco. The ore of these mines shows very little of base metals, carries native silver and silver sulphurets. At the mill is water-power all the year round. A turbine keeps an *arastra* in motion, making 15 to 20 revolutions per minute, pulverizing four to five tons per day. Here also the pulp must be dried, pulverized, sifted and roasted with salt before subjected to amalgamation in barrels. These are moved by an iron overshot wheel. The floor below the barrels, which receives the discharge of pulp and quicksilver, is made of tiles, very solid, so that no quicksilver can be lost. The floor is inclined from two sides. At the end of the channel is a round hole, deep enough to receive all quicksilver. The pulp runs over this and two more cavities of same size into a large basin of masonry, from whence it goes into the river without passing an agitator. This property, it is said, can also be bought.

There are in this district many other gold and silver-bearing ledges, worked by individuals, some showing very rich gold quartz specimens, but the beneficiation is somewhat behind time.

La Union, June 4th, 1879.

The Iron Mine Case.

The charges of Justice Miller in the case of Stevens & Leiter vs. James Williams, in which the plaintiffs obtained a second victory by the verdict of the jury in their favor, presents indications of the importance of common sense applications to the theoretical distinctions of geologists. The courts have always made it a rule to apply common sense to the law, while admitting expert testimony for information only. The workings of the Iron mine include about 4,500 feet of shafts, drifts and levels. The main incline working-shaft is situated about 300 feet from the south end-lins of the Iron claim, and extends in an easterly direction on the dip of the vein, which dips at an angle of 50° from the horizontal. The drifts and levels connecting with this main incline constitute the workings of the mine.

The defendants sank a perpendicular shaft on what they claimed as the Grand View claim, at a distance of some 450 feet east of the mouth of the main incline of the Iron mine to a depth of 200 feet, where they struck the plaintiffs vein on this main incline, on the 28th of September last. They dispossessed the plaintiffs by force, and were in their turn ousted and restrained by an injunction issued out of the United States Circuit Court. The case was tried at the last term of the court, and resulted in a similar verdict. The defendants, however, took advantage of the statute, paid the costs, and by so doing obtained a new trial which resulted again in a verdict for plaintiffs. Justice Miller in charging the jury paid a high tribute to the character of the witnesses who were miners, and treated any differences in their testimony as an error of sight or opinion only.

Attention was called to the meaning of "rock in place," and explained by the court as not meaning hard rock—mere quartz rock, but any combination of rock, broken up, once rock, mixed up with sand and other things, is rock within the meaning of the statute; and that any rocky substance containing mineral matter would also constitute rock in place. It appeared from the evidence that the strike or outcrop of this vein lies longitudinally along the claim of the plaintiffs, and such being the case they have the right to follow the vein on its dip within their projected vertical end lines. The top, apex, or outcrop of a vein is clearly, within the meaning of the statute, the end of the vein which approaches nearest the surface, although the same may be covered by debris or loose rock.

The court refused to charge the jury as instructed by defendants "that if the vein be discontinuous for a considerable distance it constitutes a break in the vein," for two reasons: "First. The words 'considerable distance' may mean nothing, or may mean a mile, half a mile, or, in a case of life or death, even half an inch might be a 'considerable distance.' Secondly. For the reason that in all veins the miners follow their lode through comparatively barren or entirely barren places; but as long as the lode, lead, or contact which the miner follows is distinct, the vein has always been regarded as one continuous vein."

The witnesses on both sides testified that the contact, which in this instance is the lode or lead, is clearly discernible throughout the mine. The plaintiffs asserted that the lime rolls and waves to the west, instead of breaking off, which the defendant denied but only theoretically. He could have easily proved his theory by obtaining an order from the court to make the necessary developments, which they should have done if the amount in controversy was as great as alleged. Section 2329 of the United States Revised Statutes defines the word "placer" clearly and unmistakably, and other deposits consequently come under the only other distinction of this law, namely, that of lodes, leads, or ledges.

The gist of the charge, as will be perceived from the abstract, is:

1. That broken rock, mixed with sand, etc., is "rock in place," within the meaning of the statute.

2. That the top, apex, or outcrop of a vein is "the end of the vein which approaches nearest to the surface."

3. That barren spaces, breaking the continuity of the paying ore bodies in a vein, do not constitute a break in this vein, if this latter (in this case, the contact) continues uninterrupted; and it would be regarded as uninterrupted although barren places existed.

The opinion of the Court as expressed in the charge goes to the point that a broken condition of rock merely does not fix it as "out of place." The statute plainly intends that the discovery of an ore deposit, not of a fraction of such deposit, or of a mass that has drifted away from it, shall decide or carry the privilege acquired by location. While it would in many cases be theoretically difficult to distinguish between veins of rock in place and placers, the court may have intended to make the distinction. The cemented conglomerates of many deep hydraulic claims are as truly rock in place as the sandstones and conglomerates of the carboniferous formations. Courts never hesitate to apply a common sense meaning to abstract and theoretical distinctions, most of which are hardly precise enough as definitions to be made available as criteria. There may be more litigation at Leadville, indeed it is a general rule that in some localities a law suit is a sort of badge of distinction.

vibration usually having a very destructive effect on the nervous system and muscular action of the animal. The severe concussion following the blow of every step upon the old style of horse shoe is entirely obviated. The new shoe gives an equal bearing around the wall of the hoof. After the yielding resistance of the downward blow, there follows a lifting power, estimated by Mr. Yates at over 200 pounds, at every step of each front foot. The increased weight in the toe of the shoe gives a firm knee action to reach out further, calculated to materially improve the gait of the horse.

This shoe is made by hand of a good tough quality of steel, and by skilled mechanics. It

YATES' HORSE SHOE.

must be put on cold, as it is tempered in oil, and a man without experience could not retemper it with any certainty of success. In ordering these shoes therefore, parties at a distance should send a paper pattern made from an old shoe.

A shoe of this kind is a cheap remedy to apply to horses' feet. The inventor states that by its use he expects to see horses trot a mile in two minutes on a hard track. He informs us that Mr. Solomon, of the Grand Central market, declares that his horse has been benefited \$75 in a month by using these shoes. And also that a three-minute horse has gained 28 seconds on spring shoes, with a decidedly improved action, increasing his value some \$200. Mr. H. G. Yates, the inventor, may be addressed at No. 263 Clementina street, in this city.

DEWEY & CO.**American & Foreign Patent Agents,**

OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

NOTICE

TO THE

MINING PUBLIC.

MESSRS. RANKIN, BRAYTON & CO., of the Pacific Iron Works, are the only parties authorized to manufacture HOWELL'S IMPROVED WHITE FURNACE under the License of this Company.

THE STETEFELDT FURNACE CO.,

By C. A. STETEFELDT, President.

Referring to the above, the undersigned would call attention to the fact that by a compromise recently effected with the STETEFELDT FURNACE COMPANY, they have secured the use of all the patents of said Company applying to

Revolving Cylinder Furnaces,

And are thus enabled to give purchasers the license of all patent claimants, to-wit:

WHITE, HOWELL, THOMPSON,

— AND THE —

Stetefeldt Furnace Company,

Thereby avoiding all further litigation in reference to these rival claims. The great

SUPERIORITY OF THE FURNACES

Embracing these patents has been satisfactorily demonstrated. There are now some thirty of them in operation in the various mining districts of the coast, operating in all cases with economy and satisfaction, working in many localities

THE BASEST AND MOST REFRACTORY ORES UP
TO 90 AND 95 PER CENT.

By an improvement—the patent for which has recently been allowed—this Furnace can be readily adjusted so as to work with equal facility and effectiveness all classes of ores.

The following are some of the Mining Companies who have recently adopted this Furnace, the most of which are now in successful operation, many of them running two and some three and four Furnaces.

NEVADA.—Grand Prize, Star, Martin White, High-bridge, Columbia, Alexander, Paradise Valley, Jefferson, Leopold, Eagle, Endowment, Independence.

ARIZONA.—Tiptop, Tiger, Peck, Hackberry, Corbin, Tombstone, Bradshaw.

OREGON.—Monumental.

MONTANA.—Alice Mine, Butte City.

MEXICO.—Trinidad, Harniguera, Plomoses.

PERU.—Cerro de Dasco.

RANKIN, BRAYTON & CO.,**Pacific Iron Works.**

CAUTION.—All persons are hereby cautioned against buying from other parties Furnaces embracing the improvements covered by the patents above mentioned, as they will be vigorously prosecuted and involved in heavy damages.

WASHING! WASHING!**Prices Reduced! Prices Reduced!****La Grande Laundry,**

13th Street, Between Folsom and Howard.

PRINCIPAL OFFICE,

648 Market Street, S. F.

Office open from 7 A. M. to 9 P. M. Saturdays to 11 P. M. Washing called for and delivered to any part of the city free of charge.

All orders receive prompt attention. For circular and price List apply at the Office,

648 Market St., San Francisco.

PALACE
RESTAURANT

This elegant and spacious S. F. Restaurant has been re-opened with superior bill of fare daily.

Good Living at Reduced Prices**218 Sansome St.**

It is now the best and most popular dining saloon on this Coast. (Lunch ready at 10 A. M.) Resident business men and visitors from abroad will be wise in giving this place an early call. Examine of fare and prices.

INVENTORS

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs,) S. F.

[CONTINUED FROM PAGE 53.]

whole of last year. The entire section of country wears a promising aspect. A new creek called Prosperine creek has been discovered, with dirt yielding from \$4 to \$6 to the pan.

COLORADO.

ITEMS.—Prospector, July 11: The Powhattan, South Powhattan and Little Annie lodes, about six miles from Silver Cliff, Custer county, have developed good mineral. A true fissure vein showing hard carbonates was discovered on the Powhattan about three weeks since, that at grass-roots assayed from \$30 to \$51 in silver and gold per ton. A tunnel has been run 65 ft into the mountain, that at a depth of 75 ft from the surface and permit the shipping of ore at once. A rich deposit of mineral, at a depth of 25 ft, has been struck, that showed good silver, arsenical iron, galena, gray copper, zinc and other minerals.

IDAHO.

SQUAW CREEK.—Statesman, July 17: Mr. G. A. Warner showed us an assay yesterday from some ore he brought in from Squaw creek, that went \$35.20 in gold, and \$172.45 in silver to the ton. Warner, Lee Moher, Hank Harvey and Dave Teichner were out on Squaw creek prospecting, and found a very well-defined lode, some four ft wide, which resembles the Bell Peck ore, in Owyhee, though no gold or silver could be seen in the rock, and most of the party pronounced it barren rock. Mr. Warner, however, brought a piece of the rock home with him, and had it assayed by Mr. Walters, with the result given above, which proves it to be wonderfully rich in silver. They found several other leads and plenty of float quartz.

MONTANA.

ITEMS.—Butte Miner, July 15: Thomas Sarvey pounded out \$3 from one pound of rock at William Sheld's mine, at the head of Spring gulch, near Summit. The miners at the head of Mill creek are taking out rich ore from the quartz lodes. Another smelter is to be erected at Glendale for reducing ore from the Elm Orlu and other mines in the Burnt Pine district. Prospecting on the river bars in the Big Horn canyon realizes from \$1.50 to \$3 per day to the hand with a rocker. The ground can only be worked during low water, as the bars are mostly covered during the spring freshets. Butte brick No. 345 was shipped last week from the Alice mine at Walkerville, weight 130 pounds. Total amount of bullion produced by this mine, in one and one-half years, 22½ tons. A new shaft 200 ft east of the old one has been started in the Stevens claim. The main shaft of the Alice has been driven down through the hard granite to the full depth of 500 ft. The force is now busy deepening the sump, which is to be sunk 20 ft below the 500 station.

NEW MEXICO.

ITEMS.—Grant County Herald, July 12: Seven silver bricks, brought in by H. M. Meredith, last Monday, aggregated 966 pounds in weight and nearly \$16,000 in value. Something over \$1,500 in gold received from Pinos Altos, during the past 10 days. The amount of silver bullion produced by the M. M. & R. W. Co. mill, during May and June, foots up 19,388 ounces. Prospecting all over George town ore. Since last published statement, I. N. Cohen has received 108,571 pounds of copper from Clinton, and shipped 118,619 pounds to the end of the railroad. Weist & Lesinsky's shipments of Longfellow copper during the past month, amount to \$6,485 pounds. During the same time, they have received 19,340 pounds.

OREGON.

ITEMS.—Sentinel, July 16: The miners on Foot's creek have about completed work for the season. All who have been able to uncover bedrock have realized good pay for their labor. This camp is rich and extensive, and though it has been worked for many years there are extensive fields of rich ground on the creek that have never been moved. Wm. Crow reports a nugget just found on Silver creek, as large as a man's hand, and worth over \$1,000. Glen cleaned up \$1,200 after a two weeks' run. Mr. Helms has a specimen of quartz taken from his claim, on Foot's creek, which weighs \$300.

ITEMS.—Times, July 18: Kretzer & Otten, mining on Farmers' flat, recently picked up a nugget of gold valued at \$120, as also other smaller pieces, one of which weighed almost an ounce. Egan & Co. are down 38 ft upon their ledge near Willow Springs, and find the vein four ft in width and still widening. The ore is of an excellent quality. Wm. Nickell, who has returned from Briggs' creek, does not give a flattering account of that section. He says the diggings are deep, hard to work, and not particularly rich in gold. Towne & Reynolds, in the Sterling district, have completed ground staking and are now engaged in cleaning up, which will occupy some time. Mr. Reynolds informs us that the spring proved an average one, the results of, which have been quite favorable.

WASHINGTON TERRITORY.

COLUMBIA MINING.—Walla Walla Union, July 12: There are from 500 to 700 Chinamen mining on the Columbia river at various points from the mouth of the Wenatchee as high up as the mouth of the Spokane river. These Chinamen have been greatly interrupted and annoyed by the Indians for several years past. So great has been the devilment committed by the savages, that many have been driven from their work and out of the country. We have been informed that there were nearly 200 left in one squad, during the troubles, two years ago. Walla Walla has been their supply point in a great measure. We saw one party shipping at one time 15 cases of gum boots, mostly for the use of the Chinese miners on the upper Columbia. They make from \$1.50 to \$2.50 a day to the hand.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco: MOUNTAIN TUNNEL GRAVEL M. Co.—Capital, \$1,000,000. Directors—H. S. McCullough, Charles H. Fish, C. F. McDermott, Everard Stede and Edward Ruhlberg. EUREKA G. & S. M. Co.—Capital, \$5,000,000. Directors—W. Meeks, John Henderson, J. H. Mayhew and William J. Gray.

FALL RIVER troubles continue; 1,000 rioters attacked a woman and her son who worked without consulting the Union. One woman and a boy won't be allowed to interfere with the rights of the downtrodden workmen at Fall River.

THERE is some excitement in Beaver county, Utah, over the discovery of placer gold mines on Clear creek, a tributary of the Sevier, about 40 miles from the town of Beaver.

THE Manufacturer and Builder says a revolution in practical metallurgy is pending, and that we must prepare for startling changes and developments.

COLORADO editors, who a short time ago stated that Leadville would this year produce \$100,000,000, have put their figures down to \$11,000,000.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

By Special Dispatch from Washington, D. C.

FOR THE WEEK ENDING JULY 15TH, 1879.

217,510.—FRUIT DRISER.—Wm. Butts, Petaluma, Cal.
217,514.—BAND SAWMILL.—S. G. Crawford and B. C. Jackson, Oakland, Cal.
217,518.—QUICKSILVER FURNACE.—J. W. Epley, Pope Valley, Cal.
217,474.—MACHINE FOR CRUSHING ROCKS.—W. C. Morrison, S. F.
217,547.—TOE-WEIGHT FOR HORSE SHOES.—A. J. Packard and C. P. Harris, Hill's Ferry, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

PORTABLE MINING FLUME.—T. Howe and N. Waite, Shasta, Cal. This invention relates to an improved method of constructing mining flumes intended for working new ground, or carrying off tailings; and it consists in the employment of a framework which is so constructed as to support the side-boards of a flume without the necessity of any bottom or the use of the bracing usually employed upon flumes, thus enabling the building of a flume by simply setting it upon the ground, and when working new ground it will gradually settle down, the earth caving into it and being washed down, until the flume has reached the bedrock; side boards being added as fast as may be necessary. The flume may be built of any width and without the necessity and expense of first excavating to the bedrock, as is now the case. The whole flume is portable and may be easily transported from one place to another by taking out the lagging screw or bolt which is used to unite the parts. The expense is very little increased by making a wide flume over a narrow one, which is one of the most important advantages of this construction.

"HOTEL AND RESTAURANT WAITER."—L. Garrigan, S. F. Dated June 17th. This is a novel device intended to facilitate the delivery of dishes in restaurants and hotel dining-rooms; and it consists of a series of shelves mounted upon a set of wheels, the whole forming a car which is easily moved about. The front wheels are small enough so that they may turn under the lower shelf, thus allowing the car to be turned in a small space. In connection with this car is used a bulletin or card made of any suitable material, on which are placed small checks or cards, each bearing the name of some dish. When an order is given this waiter puts the cards bearing the dishes ordered upon the bulletin and carries it with other orders to the kitchen, when the order is filled by the cook. This waiter has no trouble in readily delivering it to the right person who ordered, as on the bulletin is placed a series of numbers corresponding with similar numbers on the chairs at the tables, and the cards are placed opposite these numbers. This arrangement will be found very convenient in large dining-rooms, and will avoid annoying mistakes which are common with overburdened waiters.

BUTTON-HOLE MACHINE.—Justin J. Graff, S. F. Dated June 17th. This invention relates to certain improvements in machines for sewing button holes, and is more especially adapted to be used upon a machine previously patented by the same inventor. It consists in so constructing the movable cloth plate and an attached arm together with a supplementary adjustable holding plate, that the button-hole may be finished by hemming it, so that the stitching at the point shall be in line with the button-hole instead of across it.

TOE-WEIGHT FOR HORSE SHOES.—A. J. Packard and C. P. Harris, Hill's Ferry, Stanislaus county, Cal. Dated July 15th, 1879. The object of this invention is to produce a toe-weight which will adapt itself to any form of hoof and not necessitate cutting the hoof to secure it. The construction is simple, and the parts are self-binding so that they may be easily attached or removed. Weights of different sizes may be used with the same clamps if desired, thus making a very convenient and practical article.

PROPELLER PUMP.—Geo. Norton, Stockton. Dated May 20th. The peculiar construction of this propeller pump consists in the construction of a single straight cylinder having a shaft extending longitudinally through the center, and provided with propeller blades at intervals along its length. In order to avoid the employment of more than one set of screw propellers, the inventor conceived the idea of employing a longitudinal diaphragm or series of diaphragms which shall prevent any rotation and twisting in the stream.

News in Brief.

THE Nihilists have applied the torch to Nijni Novgorod.

SPAIN will be requested by England to abolish slavery in Cuba.

A FIRE at Merced on the 21st inst. destroyed \$15,000 of property.

THE Zulus seem to be desirous of peace, and many have surrendered.

THE utmost alarm prevails at the prospect of a bad harvest in France.

THE attempt to get cheap marble into the new City Hall was a failure.

A NAPOLEON V. and a Henri V. will make it interesting in France shortly.

AFFAIRS in Peru since the death of Harry Meiggs have been topsy-turvy.

SITTING BULL meditates an attack upon the army with 4,000 hostile Indians.

THE entire capital of the Panama Canal Company will be 600,000,000 francs.

A RAILROAD strike is progressing in East St. Louis among the freight handlers.

PRINCE JEROME NAPOLEON has been declared to be the head of the Bonaparte family.

ALL must register by the 9th of August or become like unto Chinamen, without a vote.

ARIZONA points with pride to its climate, it is a way-up climate—up to 120° in the shade.

FRIENDS of the dumb brutes in San Francisco investigated 720 cases of cruelty during the year.

SUFFERING Memphis is again afflicted with the yellow fever. The disease is spreading alarmingly.

THREE men were drowned in S. F. hay last Sunday, while attempting to manage a small, leaky boat.

STUDENTS in the Canadian military college are to be allowed to compete for appointment in the English army.

RUSSIA has made the Caucasus a military basis for Central Asia, and is expelling the mountaineers.

THE Sultan of Turkey is being coerced by England and France to extend the rights of Tewfik, Khedive of Egypt.

THE Porte refuses to allow the United States steamer *Quinn* to enter the Black sea because her tonnage exceeds 800.

THE criminals of Chicago have resolved to emigrate, the Chief of Police having issued an order to run them in on sight.

SERIOUS agitation exists in Westmeath and Mayo against the payments of rents, and intimidation and lawlessness are increasing.

LARGE quantities of fruits and vegetables, particularly potatoes, are being shipped at a profit from San Francisco to Denver, Colorado.

THE Putes, says the *Virginia Enterprise*, are used as bait for leeches at Pyramid lake. Leeches were never very particular about their diet.

LORD BEACONSFIELD has declared that it is generally unwise to press foreign governments too strongly on the carrying out of treaties; it must be left to moral influence.

A CYCLONE at Tucson, July 17th, struck the office of the *Weekly Star*, completely demolishing the outside of the paper and giving the inside a vertiginous twist of 180°.

BONNER'S trotter, "Edwin Forrest," made 2:15½ to wagon on a three-quarter-mile track at Tarrytown the other day; carrying Bonner himself, who weighs 180 pounds.

THE first train crossed the Colorado river and entered Arizona, on the morning of September 30th, 1877, drawn by the Engine 31, John L. Fitzpatrick, engineer.

GEO. H. PENDLETON is said to be scheming for the Presidency in 1884, by killing Thurman or putting in Tilden who will not outlive the term. This is too dreadful to be true.

THE disturbances in the Rumpa district, Madras Presidency, against the tax of palm trees, have assumed the form of an open rebellion. Of four companies of Sepoys sent there, only four men remain faithful.

THE wheat clique in Chicago has sold all of its wheat, clearing four cents a bushel profit on the corner. The same clique are now running a bull movement in western railroad stocks, with a view to control the coming crop.

THERE is considerable *obiter dicta* in the Chinese-que business, and the opinion seems to obtain credence that if the Pocasset murderer is to be punished, the queue of a Chinaman should be cut off to restore the equilibrium.

INDIA pays annually to England 15,000,000 sovereigns for interest on debt, pensions, salaries and other charges. But she has no sovereigns. The coin she possesses, provided by her government, is in silver rupees. To pay these sovereigns she must buy them in London with her silver rupees. She does this at an annual loss of 3,000,000 sovereigns.

THE century plant, better known in Arizona as *magua* or mescal, is just now decked out in its finest suit. An abundance can be found in the hills surrounding Prescott, and the blossom which only comes once in a century, killing the plant for that period, is no curiosity to Arizonians. The nectar distilled from the above plant has an electrical effect on the human system.

IN MEMORIAM.—We have received an obituary circular announcing that Jacques Antonie Moerenhout, Vice-Consul of France at Los Angeles, died at Los Angeles July 11th, 1879.

THE coinage at the United States mints during the fiscal year, ending June 30th, was as follows: Gold, \$40,986,812; silver, \$27,227,432.50; minor coins, \$97,793; total, \$68,312,042.50.

SPECIES OF EUCALYPTUS.—A New Zealand

writer sends the London *Journal of Horticulture* some notes on species of eucalyptus which he prefers to the *E. globulus*. He says: "You will find that as your *E. globulus* trees increase in age they will lose much of their present beauty, and assume a very dark green instead of the blus, and cause a good deal of labor in sweeping, as the bark and the leaves are continually falling, and look very untidy where they abound. Some of the other varieties of eucalypti are far more ornamental, in my estimation, than *E. globulus*, some of them having light and graceful foliage, and looking very feathery, more resembling the weeping willow in their habit. They are quick growers, and more hardy than *globulus*. If they were seen and found to suit your climate in England they would become general favorites for ornamental planting."

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	
1870	20	2 Complete volumes, 1st half (of year).
1870	20	2 Copies of No. 2, Jan. 1st.
1870	20	1 Copy each of No. 1, Jan. 1st, 3 of Jan. 14th, 7 Feb. 11th, 6 Feb. 4th.
1870	21	1 Copy of No. 7, August 13th.
1871	22	5 Copies of No. 1, Jan. 7th.
1871	22	3 Copies of No. 5, Feb. 4th.
1871	22	1 Copy of No. 3, Jan. 21st, 6 of Feb. 2d, and 1 of May 1st.
1871	23	1 Copy of No. 2, July 15th, and 9 Sept. 2d.
1872	24	2 Copies of No. 4, Jan. 27th.
1872	24	3 Copies of No. 7, Feb. 17th.
1872	24	3 Copies of No. 17, April 27th.
1872	25	2 Complete volumes, last half (of year).
1873	26	4 Copies of No. 8, Feb. 22d.
1873	26	3 Copies of No. 9, March 1st.
1873	26	4 Copies of No. 10, March 31st.
1873	26	2 Copies of No. 7, Feb. 15th.
1873	26	1 Copy of No. 6, Feb. 8th.
1873	27	4 Copies of No. 20, Nov. 15th.
1873	27	5 Copies of No. 21, Nov. 22d.
1873	27	4 Copies of No. 24, Dec. 13th.
1875	30	2 Copies of No. 4, Jan. 23rd.
1875	30	2 Copies of No. 8, Jan. 30th.
1875	30	1 Copy of No. 6, Feb. 6th.
1875	30	2 Copies of No. 8, Feb. 20th.

EVERY new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

Quicksilver Mining Publication.

Memoir on the Mines and Works of Almaden, by M. H. Kuss, M. E. Translated from the "Annales des Mines" for the MINING AND SCIENTIFIC PRESS, by S. B. CHRISTY. CONTENTS.—PART I.—Geological Description of the Deposits at Almaden: 1. Introduction; 2. Geological Situation and Constitution; Silurian System; Devonian System; Eruptive Rocks; 3. Deposits of Mercury; Description of the Mine; Mineralogical Constitution of the Vein Matter; Age of the Veins; Abandoned Mines. PART II.—Exploitation of the Mines of Almaden: 1. Method of Exploitation; 2. Organization of Labor; 3. Mechanical Preparation. PART III.—Metallurgy of Mercury at Almaden: 1. Description of the Works; 2. Treatment of the Ore; 3. Losses of Treatment. PART IV.—Administration and History: 2. History; 48 large pamphlet papers, post-paid, 50 cents. DEWEY & CO., Publishers, S. F., 1879.

SOUTH PACIFIC COAST RAILROAD.—This popular line has made a reduction in rates between San Francisco and San Jose and Santa Clara, to take effect April 1st, 1879, viz: Regular local tickets between San Francisco and San Jose, \$1.75; Santa Clara, \$1.65. Round trip tickets (good until used) between San Francisco and San Jose, \$3.25; Santa Clara, \$3.05. Excursion tickets sold Saturday afternoons and Sunday mornings from San Francisco and Park street, Alameda, to Santa Clara or San Jose and return, \$2.60; good only until Monday evening following date of purchase. Commutation tickets good for one round trip daily during calendar month, between San Francisco and San Jose, \$20; Santa Clara, \$19. Family tickets for 10 rides and 30 rides, also six months and yearly commutation tickets on sale at corresponding reduction in rates.

GEO. H. WAGGONER, Gen'l Pass. Agent. THOS. CARTER, Superintendent.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

RENDING, July 12th, 1879. MESSRS. DEWEY & Co.—Gentlemen:—Have received my letters patent for the bar roller to-day. I am very much obliged to you for your prompt service, and will recommend you to all who may want your assistance. I remain yours, etc., GEO. MEYING.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

PRINTER'S PROOF PRESS, complete and in good working order, for sale at this office, at the low price of \$30. Call and see it.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

(SUCCESSOR TO HAWKINS & CANTRELL).

MACHINE WORKS,

210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.

Manufacturer of

IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouse and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

Pacific Rolling Mill Co.,

SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No. 16 FIRST STREET.

Fulton Iron Works.

Hinckley, Spiers & Hayes.

(ESTABLISHED IN 1855.)

Works, Fremont and Howard Sts. | San Francisco, Cal. | Office, No. 213 Fremont St.

MANUFACTURERS OF

Marine Engines and Boilers,

Propeller Engines either High Pressure or Compound Stern or Side Wheel Engines.

Mining Machinery.

Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

Mill Machinery.

Batteries for Dry or Wet Crushing, Amalgamating

Engines and Boilers of all kinds, either for use on Steamboats and made in accordance with the Act of Congress regulating the same, or for use on land. Water Pipe, Pump or Air Column, Fish Tanks for Salmon Canneries of every description.

Boiler repairs promptly attended to and at very moderate rates.

Pans, Sottlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ore Water Jackets, Etc.

Sugar Machinery.

Crushing Rolls, Clarifiers, Vacuum Pans, Air Pumps, Concentrators, Bag Filters, Charcoal Filters, Blow-up Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.

Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Oil Well Retorts, Powder Mill Machinery, Water Wheels.

PACIFIC IRON WORKS,

First and Fremont Streets, between Mission and Howard, San Francisco, Cal.

RANKIN, BRAYTON & CO.,

Manufacturers of

ENGINES, BOILERS, MARINE AND STATIONARY. PUMPING, HOISTING, AND MINING MACHINERY

INCLUDING BATTERIES, AMALGAMATING PANS AND SETTLERS, CONCENTRATORS, ORE FEEDERS,

CRUSHING ROLLS AND ROCK BREAKERS. ALSO, WATER JACKET SMELTING FURNACES,

FOR REDUCING LEAD, SILVER AND COPPER ORES, QUICKSILVER FURNACES,

RETORTS AND CONDENSERS, ROASTING AND CHLORIDIZING FURNACES,

SUGAR MILL MACHINERY, WATER WHEELS, ETC., ALL OF THE

LATEST AND MOST IMPROVED CONSTRUCTION.

Agents for the Allen Engine Governor, Bailey Air Compressor, Howell's

Improved White Furnaces, Walker's Compound Steam Pumps, Etc.

Western Iron Works,

316 and 318 Mission Street, San Francisco,

PERRY EDWARDS, Prop'r.

Manufacturer of Wrought Iron Girders, Trusses, Prison Cells, Iron Roofs, Crest

Railings, Finials, Fences, Weather-vanes, Gratings, Iron Work for Models, Etc.

Nickel Plated Railings. Bank and Store Fittings. Estimates given and Iron Work furnished for Buildings.

Dewey & Co. { 202 Sansome St. } Patent Ag'ts. Engraving done at this office.

Corner Beale and Howard Sts.,

SAN FRANCISCO, CAL.

W. H. TAYLOR, Pres't.

JOSEPH MOORE, Sup't.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

CAST AND FORGED

STEEL SHOES and DIES,

CAMS AND TAPPETS,

Blake and other Ore Crushing Plates, Etc., for Quartz Mills. Also

Steel Cranks and Castings

Of every description. For Circulars and prices apply to

J. L. HULL,

401 Market Street, San Francisco.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Main Street Iron Works,

WM. DEACON, PROPRIETOR.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

 No. 145 Fulton St. CHICAGO, ILL.

Union Brass Foundry and Mechanical Work Shop.

GIOVANNINI & CO.,

417 and 419 Mission Street, - - SAN FRANCISCO.

The attention of our customers and especially of those interested in Water Works, Gas Works or Mines is respectfully called to our very important improvement in the construction of Stop Valves (or Gates). They differ from all others in that the inner faces are perfectly parallel, therefore when the Gate or Valve is to be opened, at the first movement of the screw the center block (see cut) releases the disks from their bearings, so that they will move easily and prevent the wearing of the inner faces.

This Gate has proved very efficient in Pipes of all sizes, and under any pressure and from its double form and perfect joint formation is especially valuable for use in large Pipes for water, steam and gas, and from its avoidance of any wedge shape cannot jam at any point (see cut).

The G. & B. Valves (or Gates) have no equal in simplicity of construction of all working parts, ease of access for repairs, and durability.

We have recently enlarged and fitted up our Brass Foundry and Shop with all the latest improved Tools and Machinery, thus greatly increasing our facilities for rapidly executing orders for all sizes of Stop Valves (or Gates) from three-inch to four feet in diameter, or any size, to order. We guarantee them to give better satisfaction, cost less money, and last longer than any other Valve in use.

We are also prepared to execute all orders in Brass Work for Breweries, Distilleries, Plumbers, Gas and Mining Apparatus, Ship Work, Soda Apparatus, Steam Fittings, Meters, Gauges and Indicators. Also in Machine Pattern and Model Making and Clock Work. Gear-cut to order. Brass Castings of all kinds. We are confident of our ability, and all orders entrusted to us will be executed with promptness and dispatch.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

MINING AND SCIENTIFIC PRESS

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers. SAN FRANCISCO, SATURDAY, AUGUST 2, 1879. VOLUME XXXIX Number 5.

An Ingenious Automatic Ventilator.

We illustrate herewith an ingeniously devised and curious automatic ventilator, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Frank J. Crouch, Eugene City, Oregon. Mr. Crouch is a young man of great ingenuity, and has invented a number of useful appliances of different kinds. This ventilator is his latest device. It is intended as an attachment to windows, transoms, etc., by means of which the opening or closing of the window or transom is automatically accomplished, in accordance with the temperature of the room.

The sash or transom is hinged or swiveled on the frame, so as to swing in a circle on a central axis, and thus be opened or closed. This sash or axis is continued through the window frame on one side. On its outer end is a pinion, which unites with a small spur wheel, as shown.

On the lower part of the frame is secured a pipe-cylinder or chamber, on top of which is a thin metallic plate. On top of this plate is another of the same size and shape, the two plates being secured together at their edges, and the space between them being filled with sulphuric ether, turpentine, alcohol or similar sensitive substance. The tube or cylinder opens into the chamber formed by these two plates through the lower plate, and also contains the ether or other substance. To the top plate of the disk is secured an arm, the upper end of which is fastened to a crank on the spur wheel.

Now, when the liquid in the cylinder expands between the plates or disks expands, the plates are expanded as they admit of a sensible spring apart at the centers. As they are expanded, they are forced apart by the expanding substance, the arm attached to the upper plate operates the crank and gear wheel, thus rotating the pinion on the shaft or trunnion carrying the sash or transom, and the sash or transom is thus swung open. As the liquid cools, the reverse is the case, and the sash is closed.

The plates and cylinders are made preferably of glass, as it absorbs heat readily, and none of the chemicals used will corrode it. No dangerous effects are produced should leakage occur.

The plate and cylinder are placed inside the room so as to be affected only by the temperature inside. When the room is heated by resultant expansion of the plates acting on the gearing will open the transom, and as the liquid cools, the plates come together, and close the transom, thus regulating the size of the opening through the transom or window in proportion to the temperature of the air. This durable and self-acting ventilator is adapted to hotels, restaurants, halls and private dwellings, where good ventilation is desirable. On one side of the window frame may be attached a gong, so arranged that in case of fire or when there is any unusual heat, the movement of the sash will ring the bell to attract attention.

EBONIZING WOOD.—W. E. D. desire to know "the details of making the so-called ebonized wood for furniture and cabinet work. What kinds of woods can be used and how the finish is put on." 1. The wood may be stained black by copperas and nutgalls, or by japaing with two coats of black japan, after which it is polished, or use size and lampblack, previous to laying on japan. 2. Collect lampblack from a lamp or candle on a piece of slate, an ordinary China dinner plate. Scrape off the deposit, mix with French polish and apply to the object in the ordinary way. Any kind of wood can be used.

DEPARTURE.—We notice the departure of Mr. Henry Woodcroft Hammond from Virginia City for England. Mr. Hammond has for many years had large transactions in the wire-rope business, both with San Francisco and New York, and has been visiting his agencies on his coast, and as we understand, taking large orders from here. He is a nephew of the late Mr. Bennett Woodcroft, who was for 25 years at the head of the British Patent Office in London.

Quicksilver Production of California.

It is a sorrowful but acknowledged fact that when an important enterprise of any kind is inaugurated and begins to establish itself upon a paying basis, the bright anticipations of the originators are sat down upon by the ubiquitous tax collector. There is neither rhyme nor reason in any indirect crushing or smothering of any business to satisfy the ever increasing and never ending demands of taxes. The goose that lays the golden egg is killed to satisfy the rapacity of tax requirements. It seems sometimes that we need more tea thrown overboard by caricature Indians in order to stop the inequality of our burdens. Our remarks are, to a certain extent, applicable to the assessments upon the quicksilver production of California.

Five counties in this State contain quicksilver mines, and, with their production for the past three years, are as follows: Napa county, Redington mine, 25,494 flasks, assessed value

immense capital may be sunk in mining property, and yet would be valued at a high figure, too high to be compatible with justice perhaps, and, in the case of our quicksilver mines, very far from the constitutional spirit of equal taxation. Our quicksilver mines deserve to be fostered, since their past has proved to be of so much importance to our general mining interests.

Footprints of Inventors.

If we could drop out of mind the mechanical world of the present and have the world of 100 years ago revealed to us, a vast and comparatively trackless plain would represent the industrial condition of the time. The only footprints visible are the shadowy ones of the geniuses of the day, searching for the connecting link between mind and matter. Coping with the material difficulties and laying aside all personal considerations, these footprints in the sand become more distinct as time approaches the

CROUCH'S AUTOMATIC VENTILATOR.

per flask \$15.89; Lake county, Sulphur Banks, 30,849 flasks, assessed value per flask \$10.08; Lake county, Great Western, 14,266 flasks, assessed value each \$9.84; Sonoma county, Oakland, 4,687 flasks, assessed value per flask \$7.11; Fresno county, New Idria, 17,846 flasks, assessed value per flask \$10.74; Santa Clara county, Guadalupe, 18,952 flasks, assessed value per flask \$13.36; Santa Clara county, New Almaden, 56,488 flasks, assessed value per flask \$17.66.

It would not be true to say that the stoppage of work on some of these mines is due wholly to the tax upon an enhanced valuation. But it is one of the reasons. Quicksilver has commercial value capable of being definitely ascertained, yet, in the valuation put upon the flasks, there are differences amounting to \$10.55. New Almaden having an assessed value per flask of \$10.55 more than the Oakland of Sonoma county.

The New Almaden has its entire property assessed upon a valuation of \$997,645, while all the other mines combined are valued at only \$1,334,894; and besides assessed per flask at \$17.66. The total production of all of the quicksilver mines amounts, for the last three years, to 168,582 flasks. A large industry, and one productive of considerable income to the State. Mining property should bear its just proportion of taxes; but there is no property in the world so difficult to assess correctly. An

present, until they become the footholds of progress, the beaten track which has led modern inventors to the apotheosis of mechanical ingenuity. The world would have existed without the inventor, a weakly, sickly world, Hamlet, with the part of Hamlet omitted. The elements of nature held in abeyance, awaiting the inventor's wand, would have rusted in oblivion, if poverty, toil and persecution had driven the inventive genius of man from the field. The element of light latent in a multitude of substances came forth obedient to the command of an inventor, and found a foothold towards progress in the lucifer match. The means of creating light called forth the inventor who could find a use for the application of that element, and illuminating facilities have developed into the brilliancy of the sun through the medium of that fearful power, electricity. And this is only a small portion of the inventive progress of man. Through all of the various gradations of progress, from the faint footsteps of the early inventor to the steady, heavy tread of the modern inventor, each one has established a foothold for the progressive discoverer of him who came next in the order of time, until it would seem as if perfection had been attained, but still the dim outline of future possibilities point the inventor incessantly to renewed exertions in solving the mysteries of the elements and in gratifying the never-ending demands of progressive humanity.

Mineral Exhibit at the Mechanics' Fair.

That the mineral products of this coast should be as fully represented as possible at the approaching exposition of the Mechanics' Institute is a proposition too obviously true to require argument. Of all our material products none more deserve to find a place in a grand display of this kind than these, none others being so generally interesting or thoroughly typical of our natural resources. What is being done officially to meet this necessity we are not fully advised. Dr. J. I. Bleasdale, who has for some time past been engaged in making a collection of minerals on this coast, will, we understand, place the same on exhibition at the Fair. This gentleman's collection, which is quite large and considerably varied, contains some specimens unique and rare, and will, so far as it goes, constitute an attractive feature in this line. This is a matter, however, that should not be left solely to private hands to be looked after, but should receive attention from the management itself.

There is in this city the material for making a creditable display in this department if only proper measures are taken for obtaining and preparing it for the use of the Institute. The Geological Society of this State has been working quietly for several years gathering ores, fossils and metals of every description. They have now on hand an immense quantity of these mineral treasures, boxed up and stored in a fire-proof building for safety. For the purpose designated the entire fruit of their labors would be placed at the disposal of the Institute, the Society being assured, of course, that they would be properly cared for and safely returned. These specimens to fit them for exhibition would require to be labeled and placed in cases, a work that could be safely committed to none but professional hands. To command the services of a proper person for this duty a suitable compensation would have to be paid; and here is where we suspect a trouble would come in, defeating the end here suggested. The management of these and similar expositions have been in the habit of getting this sort of service performed gratuitously, and looking for its continuance may be therein disappointed, for the self-sacrificing spirit of even the most enterprising becomes after a time exhausted. But this should not suffice to keep this valuable collection shut out from the public eye. Its presence would no doubt increase the receipts of the Institute beyond the cost of securing it.

In addition to this collection of the State Geological Society, or, in its absence, the splendid collection of Henry G. Hanks, might at a small outlay be secured for the uses of the Fair. This collection is very valuable and extensive, having been selected with care, and filling 40 large show cases. The Institute could hardly do less than procure this, engaging the owner to look after it while being displayed, and also give his attention, if need be, to other minerals on exhibition.

In our minerals repose the sources of our peculiar wealth, and to have them omitted or inadequately represented in a display of this kind, would evince a want of appreciation of their importance as well as a lack of State pride. We require these mineral products to be presented for inspection on these public occasions not so much as curiosities as for their economic and commercial values. Many of them are becoming important in our manufactures and useful arts and should therefore be studied and made widely known. In a large and utilitarian sense iron may be more valuable than gold, and a paving-stone of more importance than a diamond.

Bids for supplying the U. S. mints with silver bullion were opened on the 24th inst., 600,000 ounces were offered. San Francisco bids were declined, being in excess of market rates. The largest proportion of silver coinage during the month of August will be done at the Philadelphia mint, owing to the inability to procure silver at market rates for the Western mints.

An international exhibition of fishes and fisheries is contemplated at Berlin next year. Pacific coast fishes could be represented.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Publishers.

SAN FRANCISCO, SATURDAY, AUGUST 2, 1879.

VOLUME XXXIX
Number 5.

An Ingenious Automatic Ventilator.

We illustrate herewith an ingeniously devised and curious automatic ventilator, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Frank J. Crouch, of Eugene City, Oregon. Mr. Crouch is a young man of great ingenuity, and has invented a number of useful appliances of different kinds. This ventilator is his latest device. It is intended as an attachment to windows, transoms, etc., by means of which the opening or closing of the window or transom is automatically accomplished, in accordance with the temperatures of the room.

The sash or transom is hinged or swivelled to the frame, so as to swing in a circle on a central axis, and thus be opened or closed. This shaft or axis is continued through the window frame on one side. On its outer end is a pinion, which unites with a small spur wheel, as shown.

On the lower part of the frame is secured a pipe-cylinder or chamber, on top of which is a thin metallic plate. On top of this plate is another of the same size and shape, the two plates being secured together at their edges, and the space between them being filled with sulphuric ether, turpentine, alcohol or similar sensitive substance. The tube or cylinder opens into the chamber formed by these two plates through the lower plate, and also contains the ether or other substances. To the top plate of the disk is secured an arm, the upper end of which is fastened to a crank on the spur wheel.

Now, when the liquid in the cylinder and between the plates or disks expands, the plates are expanded as they admit of a sensible spring apart at their centers. As they are expanded or forced apart by the expanding substance, the arm attached to the upper plate operates the crank and gear wheel, thus rotating the pinion on the shaft or transom carrying the sash or transom, and the sash or transom is thus swung open. As the liquid cools, the reverse is the case, and the sash is closed.

The plates and cylinders are made preferably of glass, as it absorbs heat readily, and none of the chemicals used will corrode it. No dangerous effects are produced should leakage occur.

The plate and cylinder are placed inside the room so as to be affected only by the temperature inside. When the room is heated the resultant expansion of the plates acting on the gearing will open the transom, and as the liquid cools, the plates come together, and close the transom, thus regulating the size of the opening through the transom or window in proportion to the temperature of the air. This durable and self-acting ventilator is adapted to hotels, theaters, halls and private dwellings, where good ventilation is desirable. On one side of the window frame may be attached a gong, so arranged that in case of fire or when there is any unusual heat, the movement of the sash will ring the bell to attract attention.

EBONIZING WOOD.—W. E. D. desires to know "the details of making the so-called ebonized wood for furniture and cabinet work. What kinds of woods can be used and how the finish is put on." 1. The wood may be dyed black by copperas and nutgalls, or by japaning with two coats of black japan, after which varnish or polish, or use size and lamphack, previous to laying on japan. 2. Collect lamphack from a lamp or candle on a piece of slate, or an ordinary China dinner plate. Scrape off the deposit, mix with French polish and apply to the object in the ordinary way. Any kind of wood can be used.

DEPARTURE.—We notice the departure of Mr. Henry Woodcroft Hammond from Virginia City for England. Mr. Hammond has for many years had large transactions in the wire-rope business, both with San Francisco and New York, and has been visiting his agencies on this coast, and as we understand, taking large orders from here. He is a nephew of the late Prof. Bennett Woodcroft, who was for 25 years at the head of the British Patent Office in London.

Quicksilver Production of California.

It is a sorrowful but acknowledged fact that when an important enterprise of any kind is inaugurated and begins to establish itself upon a paying basis, the bright anticipations of the originators are sat down upon by the ubiquitous tax collector. There is neither rhyme nor reason in any indirect crushing or smothering of any business to satisfy the ever increasing and never ending demands of taxes. The goose that lays the golden egg is killed to satisfy the rapacity of tax requirements. It seems sometimes that we need more tea thrown overboard by caricature Indians in order to stop the inequality of our burdens. Our remarks are, to a certain extent, applicable to the assessments upon the quicksilver production of California.

Five counties in this State contain quicksilver mines, and, with their production for the past three years, are as follows: Napa county, Redington mine, 25,494 flasks, assessed value

immense capital may be sunk in mining property, and yet would be valued at a high figure, too high to be compatible with justice perhaps, and, in the case of our quicksilver mines, very far from the constitutional spirit of equal taxation. Our quicksilver mines deserve to be fostered, since their past has proved to be of so much importance to our general mining interests.

Footprints of Inventors.

If we could drop out of mind the mechanical world of the present and have the world of 100 years ago revealed to us, a vast and comparatively trackless plain would represent the industrial condition of the time. The only footprints visible are the shadowy ones of the geniuses of the day, searching for the connecting link between mind and matter. Coping with the material difficulties and laying aside all personal considerations, these footprints in the sand become more distinct as time approaches the

CROUCH'S AUTOMATIC VENTILATOR.

per flask \$15.89; Lake county, Sulphur Banks, 30,849 flasks, assessed value per flask \$10.08; Lake county, Great Western, 14,266 flasks, assessed value each \$9.84; Sonoma county, Oakland, 4,687 flasks, assessed value per flask \$7.11; Fresno county, New Idria, 17,846 flasks, assessed value per flask \$10.74; Santa Clara county, Guadalupe, 18,952 flasks, assessed value per flask \$13.36; Santa Clara county, New Almaden, 56,482 flasks, assessed value per flask \$17.66.

It would not be true to say that the stoppage of work on some of these mines is due wholly to the tax upon an enhanced valuation. But it is one of the reasons. Quicksilver has commercial value capable of being definitely ascertained, yet, in the valuation put upon the flasks, there are differences amounting to \$10.55. New Almaden having an assessed value per flask of \$10.55 more than the Oakland of Sonoma county.

The New Almaden has its entire property assessed upon a valuation of \$997,645, while all the other mines combined are valued at only \$1,334,894; and besides assessed per flask at \$17.66. The total production of all of the quicksilver mines amounts, for the last three years, to 168,582 flasks. A large industry, and one productive of considerable income to the State. Mining property should bear its just proportion of taxes; but there is no property in the world so difficult to assess correctly. An

present, until they become the footholds of progress, the beaten track which has led modern inventors to the apotheosis of mechanical ingenuity. The world would have existed without the inventor, a weakly, sickly world, Hamlet, with the part of Hamlet omitted. The elements of nature held in abeyance, awaiting the inventor's wand, would have rusted in oblivion, if poverty, toil and persecution had driven the inventive genius of man from the field. The element of light latent in a multitude of substances came forth obedient to the command of an inventor, and found a foothold towards progress in the lucifer match. The means of creating light called forth the inventor who could find a use for the application of that element, and illuminating facilities have developed into the brilliancy of the sun through the medium of that fearful power, electricity. And this is only a small portion of the inventive progress of man. Through all of the various gradations of progress, from the faint footsteps of the early inventor to the steady, heavy tread of the modern inventor, each one has established a foothold for the progressive discoveries of him who came next in the order of time, until it would seem as if perfection had been attained, but still the dim outline of future possibilities point the inventor incessantly to renewed exertions in solving the mysteries of the elements and in gratifying the never-ending demands of progressive humanity.

Mineral Exhibit at the Mechanics' Fair.

That the mineral products of this coast should be as fully represented as possible at the approaching exposition of the Mechanics' Institute is a proposition too obviously true to require argument. Of all our material products none more deserve to find a place in a grand display of this kind than these, none others being so generally interesting or thoroughly typical of our natural resources. What is being done officially to meet this necessity we are not fully advised. Dr. J. I. Bleasdale, who has for some time past been engaged in making a collection of minerals on this coast, will, we understand, place the same on exhibition at the Fair. This gentleman's collection, which is quite large and considerably varied, contains some specimens unique and rare, and will, so far as it goes, constitute an attractive feature in this line. This is a matter, however, that should not be left solely to private hands to be looked after, but should receive attention from the management itself.

There is in this city the material for making a creditable display in this department if only proper measures are taken for obtaining and preparing it for the use of the Institute. The Geological Society of this State has been working quietly for several years gathering ores, fossils and metals of every description. They have now on hand an immense quantity of these mineral treasures, boxed up and stored in a fire-proof building for safety. For the purpose designated the entire fruit of their labors would be placed at the disposal of the Institute, the Society being assured, of course, that they would be properly cared for and safely returned. These specimens to fit them for exhibition would require to be labeled and placed in cases, a work that could be safely committed to none but professional hands. To command the services of a proper person for this duty a suitable compensation would have to be paid; and here is where we suspect a trouble would come in, defeating the end here suggested. This management of these and similar expositions have been in the habit of getting this sort of service performed gratuitously, and looking for its continuance may be therein disappointed, for the self-sacrificing spirit of even the most enterprising becomes after a time exhausted. But this should not suffice to keep this valuable collection shut out from the public eye. Its presence would no doubt increase the receipts of the Institute beyond the cost of securing it.

In addition to this collection of the State Geological Society, or, in its absence, the splendid collection of Henry G. Hanks, might at a small outlay be secured for the uses of the Fair. This collection is very valuable and extensive, having been selected with care, and filling 40 large show cases. The Institute could hardly do less than procure this, engaging the owner to look after it while being displayed, and also give his attention, if need be, to other minerals on exhibition.

In our minerals repose the sources of our peculiar wealth, and to have them omitted or inadequately represented in a display of this kind, would evince a want of appreciation of their importance as well as a lack of State pride. We require these mineral products to be presented for inspection on these public occasions not so much as curiosities as for their economic and commercial values. Many of them are becoming important in our manufactures and useful arts and should therefore be studied and made widely known. In a large and utilitarian sense iron may be more valuable than gold, and a paving-stone of more importance than a diamond.

Bids for supplying the U. S. mints with silver bullion were opened on the 24th inst., 600,000 ounces were offered. San Francisco bids were declined, being in excess of market rates. The largest proportion of silver coinage during the month of August will be done at the Philadelphia mint, owing to the inability to procure silver at market rate for the Western mints.

An international exhibition of fishes and fisheries is contemplated at Berlin next year. The Pacific coast fishes should be represented.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds

Mining and Prospecting in Fresno Co.

EDITORS PRESS:—Disastrous to the farming interests of most of San Joaquin valley as is the present dry year, following so soon the dry year of 1877, it is not an unmitigated evil, because it has tended to develop the mining resources of our southern counties. The necessity for sheep raisers to take their stock for feed to the higher mountain regions summer after summer, has not only called attention to the inexhaustible belts of the finest timber in the Sierras, but is occasionally leading to the discovery of valuable mineral ledges. In years of usual prosperity to stock and grain raisers but little thought is given to the ore veins found by sheepmen in their mountain wanderings, but a year like this makes many a farmer desert his unprofitable grain fields, and with necessary outfit of supplies and prospecting tools, follow our mountain streams to their sources in quest of gold and silver-bearing quartz ledges; some perhaps formerly found but almost forgotten, others to be discovered for the first time by white men. The year 1879 will long be remembered for the large amount of prospecting done by former miners and others who have been following the plow of late years. This rush for the mountains and eager search for fissure veins, charged with the precious metals, began to some extent last year, and are already producing promising results, of which this and one or two succeeding letters will aim to give your readers some account. In Fresno county it is especially true, not only that some fine ledges are being discovered, but that several old mines are being more thoroughly and successfully worked. Former failures in some mining projects in this county had, until recent development, generally destroyed confidence in Fresno as a mining region. But now, in a quiet way, Fresno prospectors and miners are putting in some good work, and results are likely to surprise the mining world.

The Two Centers

That are especially attracting attention in mining circles here just now are the regions around Fresno Flats, and the North Fork and Minaret districts, along the headwaters and tributaries of the Fresno and San Joaquin rivers. The former district is from 30 to 45 miles northeast of the railroad stations of Borden, Madera and Berenda; the other two districts about 50 miles farther east and northeast, near points of location to be known hereafter as Highland City and Miaret City. The latter points are within from six to ten miles of Mammoth City, Mono county, in the now noted Lake district, and their interests will form the subject of a separate letter.

By common consent, the

Enterprise Mine

Is the richest yet developed in the mountains around Fresno Flats. It is located on the south side of Fresno river, about six miles below or southwest of the town of Fresno Flats. It was discovered in October, 1877, by E. B. Lovelace, a young man without experience in mining, who concluded to try his fortune at prospecting. He and his partners, Chivell and Carrol, put up a simple arastra run by an overshot water-wheel 28 feet in diameter. By it they saved an average of about \$40 per ton, and continued working the mine until August, 1878, when they sold it to John Haley, the present Superintendent, a well-known mining engineer, who bonded and took charge of it in behalf of the present company. A tunnel, that had been run in 25 feet, has been extended by Mr. Haley to 150 feet in length, or 90 feet under ground. The ledge, whose gangue rock is talcose slate, is from 3 to 12 feet wide and its dip is 70°. It is an interesting fact, that the celebrated Hite mine of Mariposa county is only some 14 miles distant in a direct line northeast, and that the ore of the Enterprise and Hite mines are very similar. The arastra and office are located about 2,900 feet above sea level, but a short distance above bed of river. The ledge runs diagonally across the hill to an altitude of some 4,100 feet, the hill facing northward with an inclination of about 45°.

From north to south the following

Openings Have Been Made

Under Mr. Haley's directions, some 18 men being employed about the mine at present:

1. There is a winze down on the vein 50 feet. Thence a level is run north 43 feet. Here the ledge is six feet wide. This develops the richest free-milling ore yet found in this mine, averaging some \$400 per ton.
2. The ledge has been opened by cuts every 15 feet from that winze to center of claim.
3. At the center a winze is down 90 feet, intersecting the north end of tunnel already described. From the bottom of the tunnel the winze is extended 48 feet.
4. From center all along the line of ledge, openings are made at different intervals to the extreme south end of claim, where a shaft has been sunk at an angle of 70° to depth of 36 feet. The entire extent of the claim is the usual 1,500 feet, but Mr. Fairbanks, President of a

hank in Petaluma, and a shareholder in the Enterprise, has lately bought this northern extension of the ledge, 1,500 feet more, which also prospects very favorably.

5. A tunnel is being run to strike the center of the Enterprise at a depth of 500 feet. It was commenced last March, and 300 feet are already completed. Another tunnel will be run near the north end to strike the ledge at a depth of 1,000 feet.

Your readers will see that these various openings will command a large body of ore. The ledge is already proved to be a true fissure vein. Ore from most parts of the ledge has been tested in the arastra to the amount of several hundred tons, and none has produced less than \$41 per ton. No ore has as yet been worked by any means but the arastra, whose capacity is a ton and a half per day. But ore from the deepest part of ledge reached by tunnel, and which contains sulphurets from which the surface ore is clear, has been assayed, and yields from \$500 to \$900 per ton. It is proposed to put up a stamp mill, so soon as ore is struck by the tunnel now in course of construction, and is found to be valuable. It will be located near the mouth of central tunnel. It is safe to say that, if the ore at 500 or 1,000 feet proves to be half or a fourth as good as the surface ore, the Enterprise will be one of the most valuable mines in California. The gold from this mine is remarkably fine, its value being \$19.16 per ounce. This surface quartz, containing it in large flakes and grains, is glossy, and very much reddened by oxide of iron. In short, it is just such quartz in appearance, as most miners would pass by as unworthy of notice. At greater depths the quartz becomes whiter. It and the gangue rock enclosing it are very similar in general appearance to that from A. O. Bell's mine near Auburn, Placer county, which I described in your columns two years ago.

The Confidence Mine

Is located about 12 miles, by road, below Fresno Flats. It is owned by Messrs. Carroll, Morton and other parties, near Merced City. No work is going on there at present, but Mr. Morton informs me that the company proposes to renew operations soon. A 10-stamp mill has been erected there. Part of their ore has produced as much as \$200 per ton, and the ledge is generally considered a good one.

The Texas Flat Mine

Is located in Coarse Gold gulch, some six miles southwest of Confidence mine. A shaft 185 feet deep has been sunk there but no work is going on at present, except to keep the shaft from filling with water.

Spangled-Gold Mine.

On a gulch of the same name, is nine miles west of the Confidence. It is owned by Messrs. Hogue & Wagner. Its ledge is from two to five feet wide. A tunnel and cut along the ledge have been completed some 250 feet, and part of the ore milled has averaged \$55 per ton. A two-stamp and two arastras are now in operation there.

In and near

Fine Gold Gulch.

About 15 miles southeast of Fresno Flats, several mining enterprises are being pushed ahead steadily. Near Quartzburg are the shafts, tunnel and 5-stamp mill of the Fresno gold mining company. Their mill was erected over a year ago, and is run by water power. They think of doubling the number of stamps soon. Eleven shafts have already been sunk from 50 to 100 feet. A tunnel has been completed 100 feet, following a quartz lode in granite walls, and has developed some of the best ore yet found. In the latter silver has been discovered for the first time in this locality, the ore yielding about \$57 in gold and \$21 in silver. Since March last a considerable amount of decomposed quartz has been found in all the shafts, and this contains some free gold. The average of such ore as has been worked is about \$30, some going as high as \$400 per ton. Altogether the mine is yielding satisfactorily. In width the vein in the tunnel varies from six inches to four feet; in the shafts from eight inches to four feet. It is believed that all ore yet found here is merely from surface ledges, and the owners are still searching for the mother vein. Messrs. De Fries & Hazeltine, the principal owners, are now East. On their return it is proposed to run a tunnel for the purpose of cutting the main lode at the depth of 400 feet.

About a half a mile above this company's mill Messrs. Hampton & Galt are working the "White Rock Vein." A tunnel for drainage is already in 260 feet. Theirs is free milling ore containing some sulphurets and oxide of iron; also some decomposed quartz. Five or six men have been employed on this work since April. An assay in May gave \$283.77 gold and \$13 silver, as I am informed by Mr. John Galt. Part of their ore is crushed in their own arastra, though some of it is crushed by the Fresno company's mill. Mr. W. P. Litten, foreman at the mill, also has charge of the

Quartz Mountain Works.

Quartz mountain is about three miles west of Quartzburg. Mr. Litten informs me that some 20 acres of gold-bearing quartz are exposed on this mountain, that it is generally low grade ore on the surface, averaging from \$6 to \$18 per ton. The vein is from 2 to 14 feet wide, has a general dip of 40° northward, and shows no signs of silver as yet. The right to 3,000 inches of water has just been located to run a large stamp mill soon to be erected at Quartz mountain. By aid of pipe and flume this water will be conveyed over 14 miles from a tributary

of the San Joaquin. Another company has commenced a tunnel opposite Quartzburg to reach the Indicator ledge, and the Harlow, Lewis and Baker ledges, not far from the same locality, are said to prospect favorably.

You see then that the mining interests of this part of Fresno county are no longer slumbering, but that a renewed activity prevails, and results are obtained which augur well for the future.

J. W. A. W.

Fresno Flats, July 3d.

How to Explore for Minerals.

Mr. J. E. Clayton, mining engineer, contributes to the Salt Lake (Utah) Tribune, the following items on prospecting for minerals:

1st. Examine the gravel and boulders of the mountain streams, and note carefully the structure and character of the gravel wash. This will reveal the geological formations that are intersected by the stream. Try the sands at the head of the gravel bars for free gold, or for any crystallized minerals, etc. If the structure of the quartz boulders or other vein stones are favorable, go up the stream until the geological zone is found that has produced the quartz or other metal-bearing minerals. Then follow the supposed metal-bearing zone on its line of strike and make especially careful examinations wherever eruptive dikes are found intersecting the formation.

2d. When a lode or vein is found, note carefully its relation to the country rock, especially any differences in the opposite walls of the vein. Then follow it on the line of outcrop, and note carefully those points where the best ores are seen, so as to determine the position of the best ore-chutes before making any location on the lode.

3d. The first work should consist of shallow cuts across the lode at intervals of 50 to 100 feet, or, if the vein is small and partially covered by soil and debris, a trench along the line of outcrop is preferable. If the surface tracing is satisfactory and the true line of strike has been determined, then survey your claim and stake off the boundaries according to the requirements of the United States laws.

4th. The work of exploring the vein underground is the next thing in order. To do this intelligently, you must select that point on the line of outcrop where the best ore is found, then sink a shaft on the lode following the angle of dip, keeping both foot wall and hanging wall exposed if possible. If the lode is too wide for this to be done, then follow the best ore streak of the vein itself, and at every 50 feet in depth make crosscuts to the walls of the vein. After 100 feet has been reached, run levels each way from the shaft on the line of the vein, in order to determine the extent or spread of the ore, chute or chimney on the horizontal line. When the limit of the ore body on the horizontal line has been ascertained, then sink 100 feet more, and drift right and left as before. If more than one chimney of ore is found on the line of this vein, a shaft should be sunk on it and drifts run as above stated, being careful to confine all the exploring work within the walls of the vein itself. When enough has been done to prove the character, size, and quality of the vein, it will then be time to determine the position, character, and extent of the "dead work" necessary to work the mine to the deep. These questions should be settled by careful surveys, made in the light of all the local facts and surroundings, such as the geological structure of the country rock, the probable amount of water to be raised, the lowest point of drainage by adit, or level, and the most convenient point for delivery of the ores to the surface, etc.

The last part of the preliminary exploration of any mine is to determine, by actual tests, what are the best methods of reduction, and the extent and kind of reduction works needed, etc. 5th. After all these preliminary facts have been thoroughly ascertained and clearly defined, the unavoidable risks of mining will have been fully met and overcome. All subsequent operations are simply matters of skill and business management, and the capitalizing of the mine becomes a mere matter of business detail.

The requirements are as follows:

1st. The preliminary exploration must have ore enough cut and undermanned, or otherwise exposed, to give at least two years' work for reduction works of an extent sufficient for the average annual output of ore.

2d. The reduction works must be suited for the best treatment of the ore.

3d. The exploration of the mine must be pushed ahead of extraction of ore, so as to expose at least one ton of ore in new ground, for every ton extracted from the previously explored ground.

4th. Before erecting reduction works, the ore exposed in the mine should be so thoroughly tested as to guarantee a net profit sufficient to pay the whole cost of such works.

5th. The mine being well opened, and the reduction works, or plant, established, the general success of the enterprise must depend upon the efficiency of the general business management.

Snake River Mining.—The claims are located in 20-acre lots, principally owned by San Francisco and Salt Lake capitalists. The country is said not to be desirable for prospectors. The gold, however, is very fine, but can only be saved by using the electro-plate.

Rights of Ditch and Canal Owners.

In 1873, S. Jennison, the testator of R. B. Titcomb, constructed a ditch in Placer county, California, to convey the waters of a canyon to a mining locality known as Georgia hill, 17 miles distant, for mining, milling and agricultural purposes, and for sale. The intention of the testator when he appropriated the water right was to divert 2,000 inches of the water of the canyon by means of a flume and ditch. In its course, the ditch crossed Fulweiler's gulch, the waters of which had been already appropriated by J. T. Kirk, who had constructed ditches, one of which was intersected by the testator's ditch, which diverted the waters from it. Kirk thereupon repaired and reopened his own ditch, turning into it the waters which had previously flowed in it, and in so doing cut and washed away a portion of the ditch of the testator, so as to let out the waters brought down from the canyon above and the intermediate streams. The testator brought suit against Kirk for damages and to restrain the continuance of the injury to his ditch. The case was carried to the Supreme Court of the United States and is the case entitled S. Jennison, executor of R. B. Titcomb, vs. J. T. Kirk.

It appears from the answer of Kirk, which the court finds to be correct in this particular, that he and his predecessors in interest had been in possession of a portion of Fulweiler's gulch for many years prior to this suit, and the ground was continuously held and worked for mining purposes, and as a mining claim, according to the usages, customs and laws of miners in force in the district; that the "hydraulic process" was used in working the claim and extracting the gold, for which a large volume of water was necessary; and that the plaintiff's ditch rendered the gold-bearing earth and gravel inaccessible, and practically destroyed the working of the mining ground.

It was admitted that defendant's right of way for his ditch was superior to that of plaintiff; and it was also admitted that the extension of plaintiff's ditch across the defendant's claim prevented the successful working of the mining claim. But it was contended that as the land over which the ditch passed and on which the claim is situated was a portion of the public domain of the United States, that the right of way for the ditch was superior to the right to work the claim, such superior right being conferred by the ninth section of the act of Congress of July 26th, 1866. That section enacts:

That whenever, by priority of possession, rights to the use of water for mining, agricultural, manufacturing, or other purposes, have vested and accrued, and the same are recognized and acknowledged by the local customs, laws, and the decisions of courts, the possessors and owners of such vested rights shall be maintained and protected in the same; and the right of way for the construction of ditches and canals for the purposes aforesaid, is hereby acknowledged and confirmed: Provided, however, that whenever, after the passage of this act, any person or persons shall, in the construction of any ditch or canal, injure or damage the possession of any settler on the public domain, the party committing such injury or damage shall be liable to the party injured for such injury or damage.

The court pronounced the plaintiff's position untenable and held: 1. That this section only confirms to the owners of water rights and of ditches and canals on the public lands of the United States the same rights which they held under the local customs, laws, and decisions of the courts, prior to its passage; and, 2. That the proviso confers no additional rights upon the owners of ditches subsequently constructed; but simply renders them liable to the parties on the public domain whose possessions may be injured by such construction.

The section is to be read in connection with other provisions of the act of which it is a part, and in the light of matters of public history relating to the mineral lands of the United States. The law of miners recognized discovery, followed by appropriation, as the foundation of the possessor's title, and development by work as the condition of its retention. By that law the owner of a mining claim and the owner of a water right in California hold their respective properties from the dates of their appropriation, the first in time being the first in right; but where both rights can be enjoyed without interference with or material impairment of each other, the enjoyment of both is allowed.

By that law a person cannot construct a ditch to convey water across the mining claim of another, taken up and worked according to that law before the right of way was acquired by the ditch owner, so as to prevent the further working of the claim in the usual manner in which such claims are worked, nor so as to cut off the use of water previously appropriated by the miner for working the claim, or for other beneficial purposes.

Accordingly, where the owner of a mining claim worked by the method known as "the hydraulic process," cut and washed away a portion of a ditch so as to let out the water flowing in it, the ditch having been so constructed across the claim previously acquired as to prevent it from being further worked by that method, and to prevent the use of water previously appropriated by him. Held, that the cutting and washing away of the ditch, it having been done in order that the claim might be worked and the water used as before, was not an injury for which damages could be recovered. And judgment in favor of defendant was affirmed.

MECHANICAL PROGRESS.

The Electric Light in Photography.

The idea of photographing by the electric light has long been entertained, but the light emanating from a single point renders the shadows too abrupt, and the contrasts too great, to admit of using it in making photographic portraits. Recently, however, the invention of our countryman, Mr. Vander Weyde, for some time in practical use in London, has been introduced in Paris by Mr. Liebert, which diffuses the light, renders it soft and mellow, and imparts to it the particular quality required in making photographic portraits. Not long since we alluded to the fact that it had become quite the fashion in Paris for parties of ladies and gentlemen to resort to photographic studios, after dinner or before the opera, for the purpose of sitting for photographs.

The light used for the purpose is that of the voltaic arc, the lamp being placed in the huge concave reflector suspended by a system of pulleys, levers and counter-weights, so that it may be readily adjusted or moved about. The reflector is made of opaque porcelain, lined with paper stucco, which is tinted blue. The carbon pencils between which the voltaic arc is formed are placed almost at a right angle to each other. The light has normally a power equal to about 300 or 400 Carcel lamps, but it can be made more powerful by increasing the speed of the Gramme machine.

The light of the voltaic arc is twice reflected. A small reflector placed in front of the lamp throws the light upon the interior surface of the large reflector, whence it is thrown in any required direction according to the will of the operator. The carbons are adjusted by means of screws, so that the maximum effect of the current may be realized, and flickering and variations in the light avoided. The Gramme machine used in connection with this apparatus is driven by a five horse-power gas motor.

A photographer provided with this apparatus is not at the mercy of the weather, neither is he controlled by the time of day, as he has the absolute management of the light. This arrangement of the electric light might be used to advantage in illuminating public places, railway stations, theaters, etc., as the light is very powerful, and yet so diffused that it does not pain the eye.—*Scientific American*.

ELECTRO ENGRAVING MACHINE.—It has baffled the skill of inventive genius for ages, to produce a machine that would compete with the skillful hand engraver. Guérant, after much study in trying to perfect such a machine, has, by the aid of electricity, succeeded in producing a practical machine, which it is claimed has no rival. The construction of the machine is not complicated, but simple and durable. It is easily operated—any person of ordinary mechanical skill can learn to work it in a short time. There is nothing to do but turn a crank forward and back, after the work is fixed in the machine. The variety of work that may be accomplished by it is said to be unlimited. It copies from the regular press type of any style of letter or design that is made of type; from the plainest to the finest German text letter, or fancy design; and at the same time, it will reduce the letter or design from the original size to ten different sizes, or so small that it cannot be seen by the natural eye. It will shorten the letters or elongate them; also, will lean them forward or backward; will either make a raised or sunken letter; will engrave on any surface, either plain, concave or convex—for instance, such things as watch-cases, either in or outside, finger rings, either in or outside, bracelets, napkin rings, goblets, pitchers, mugs, waiters, spoons, forks, and all kinds of jewelry; or, in fact, any article susceptible of being engraved or ornamented with scroll-work and fancy designs, etc., either on gold, silver, copper, brass, iron, hardened steel, glass, stone, pearl, ivory, bone, gutta-percha, etc. The machine is capable of doing the most difficult kinds of engraving, and on the most difficult metals and substances to be engraved.

A NOVELTY IN LAMPS.—The Committee of Science and the Arts of the Franklin Institute lately passed a very favorable judgment upon a mechanical lamp of peculiar construction, known as the Hitchcock lamp, and designed to burn heavy fat or greasy oils without a chimney. Mechanical lamps are not altogether new. The well-known Carcel lamp, the oldest, and perhaps the best known of its class, which is also designed to burn fat oils, is provided with a mechanical movement which pumps the oil up to the wick from the lamp body, while the air-supply is obtained by the use of a chimney of glass. An American lamp (the immediate predecessor of the Hitchcock), known as the Jones & Hitchcock lamp, is designed to burn kerosene without a chimney, and effects its object by means of a mechanical movement, which (unlike the Carcel) furnishes the air-supply to the flame, the oil being supplied to the wick by capillary action. The Hitchcock lamp presents the novelty that the mechanical movement performs both these functions—supplying the air and feeding the oil simultaneously. The committee's report makes special reference to the mechanical excellence displayed in its construction, and places its illuminating power, when consuming 922.4 grains of lard oil per hour, at

16.9, or nearly 17 candles. The form of lamp examined by the committee was designed especially for railway cars.

IMPROVEMENT IN ELEVATED RAILROADS.—Peter Cooper, of New York, makes the subject of a long letter, addressed to the press, the improved methods of rapid transit. To obviate the annoyances attendant on the present system of elevated railroads, he advocates the adoption of a plan of which the salient feature is the use of an endless chain. After considering the advantages of this method of propelling the cars, he recommends a plan for the noiseless running of the cars over the rails. The constant pounding of the wheels in passing from one rail to another is to be avoided by the use of a chair which will give support to the wheel. The wheels themselves are to be made with a groove over the whole face, which is filled with hard gutta-percha. "An elevated railroad so constructed," Mr. Cooper says, "with the propelling power under the ground, and the rails so arranged as to take up the momentum in stopping and hold it ready to be given out in starting, with the wheels of the cars covered with gutta-percha, working on gutta-percha covering, and the rail held in a firm grasp in an India rubber chair, so that it would not touch iron in any of its parts, would have nothing to convey sound except the mere rubbing of the flange against the side of the rail. This rubbing could be avoided mainly by the shape of flange." The advantages claimed for this method of rapid transit are the small cost of operating, absolute safety, and the perfect freedom from noise, sparks, dust and gases.

A LARGE SUGAR MILL.—One of the largest sugar mills in the world is soon to be erected in St. Charles parish, Louisiana. The total weight of this mill, including engine, will be 300,000 pounds. The latter will be of about 300 horse-power. The rollers are to be seven feet long and 40 inches in diameter, weighing each 18,000 pounds, or all 54,000 pounds. The shafts are of wrought-iron, 18½ inches in diameter and 20 inches long. The housings, made of the best gun-metal, are each 14 feet long, with 18-inch face, and will weigh 54,000 pounds. The mill will be double-geared—that is, run with two sets of pinions and spur-wheels of enormous size and weight. The shafts of all these wheels, with that of the fly-wheel, will be of the best wrought-iron, while the journal bearings of the roller shafts in the housings will be manufactured of the purest Babbitt metal. It is estimated that with this machinery there will be a gain of more than 30% on the work of the ordinary mills. A number of single or three-roller mills and a few five-roller mills have been erected in the State recently.

WRITING TELEGRAPH.—The writing telegraph which reproduces the messages sent, in almost perfect *fac simile* of the sender, has been fitted up between Waterloo and Woking, a distance of some 26 miles, and according to the *Ecce* has been working very well. The instrument itself is too recent an invention to have yet reached even an approach to perfection, but the defects made evident in practical working have so far been remedied, and it is clear that a useful improvement will shortly be available. One great advantage is that the instrument is quite automatic at the receiving end, and does not require the constant attendance of a clerk. It writes in messages on a roll of paper, and they can be cut off and sent to their destinations as opportunity offers. That is an important point, because it is well known that the time wasted in calling and in obtaining the attention of the receiver far exceeds that required for the actual sending of the messages.

EDISON'S ELECTRIC-CHEMICAL TELEPHONE.—This new invention of Mr. Edison dispenses with the necessity of holding the telephonic receiver to the ear, and besides furnishing a greater volume of sound, renders distinct the slightest peculiarities of the voice. It has been found to work perfectly at a distance of 50 miles. The improvement consists in causing the current to pass through a pool of chalk containing crystallized caustic soda, and having a thin tongue of steel resting upon. The chalk is mounted on a shaft turned by a crank, thus creating friction, and when so operated, the current passing through the pool, polarizes the chemical agent, and is thence transmitted through the steel tongue to a thin metallic diaphragm. The current only flows so long as the crank is turned. It is Mr. Edison's intention to furnish clock-work for the mechanical movement, so that it may be stopped and started by electricity at the will of the operator.

INVENTIONS.—F. M. Wilson, of Tekamah, Nebraska, has invented an improvement in windmills, consisting of an arrangement of an eccentric and double-crank shaft, by which it is claimed a much larger percentage of power is realized than in the ordinary mills. An improved wharf for rivers, harbors and lakes is a new invention of Mr. S. Howell, of New Orleans. It consists in the combination of metal straps with the mortised cross pieces and stringers of a wharf, and other novel features of construction, which render it possible to build wharfs of any desired length and size in a shop or enclosure and afterward to put them up very quickly. An improved oscillating pump has been devised by Daniel Palacios, of New York city. The pump cylinder is connected at its lower end with a hollow rock shaft or pipe, which communicates with the pump valves. The piston rod is connected with a crank on the pump-driving shaft.

SCIENTIFIC PROGRESS.

Heat and Electricity.

Mons. Clamond, a French electrician, has succeeded in producing valuable lighting effects from his thermo-electric pile. This is a confirmation of the fundamental laws of energy, viz., that all forms of energy are convertible.

In every electro-dynamic machine now in use considerable loss occurs at every conversion and re-conversion of energy or motion. There is a loss of 90% of the source of energy in the dynamo-electric plant. No machine in the market realizes more than from 25% to 30% in electrical energy units, of the mechanical energy units required to drive it. The balance is lost in the friction and resistance of the high speed at which the machine must be driven, and in the loss by leakage, and in the opposition of the electric currents generated.

Hence, the deplorable result, that in the usual dynamo-electric plants there is not more than 2½ or 3% of the original heat energy realized as electricity.

Thermo-electricity is the branch of electricity in which least is known, and in which hardly any data have been given to the world. It had been discovered long ago that when two diverse metals were united and subjected to heat at their junction, a current of electricity was generated from one metal to the other, and this was called thermo-electricity. The amount and character of this electric current is found to vary with every variation in the particular metals used, and also with their shape and area. Although the principal metals have been arranged in an order as to their relative so-called plus and minus qualities, and it has also been defined that the current of electricity is better, as the pair have most opposite characters to one another, we believe that there have never been any published definitions as to what constitutes the plus or minus character of the metals, or in what way the current may be affected by the shape, area, thickness or method of connection of the pairs, constituting a pile or battery when in combination.

There is thus an enormous field of research open in this direction, and we believe an excellent reward for those who may discover the above laws. By the use of a thermo-electric battery, one very large source of loss will be eliminated altogether, compared with a dynamo-electric machine. The 90% loss due to the use of a boiler and steam engine may thus perhaps, in a considerable degree, be saved. The economy of the arrangement would depend upon whether the fuel or heat could be retained in contact with the metal pairs, so that the largest possible proportion should be absorbed, and that the electricity should be generated of the particular character required, and without leakage or polarization of the couples.

Electro-dynamic machinery is only the commencement of a successful grappling with the problem of electric lighting.—*Universal Engineer*.

UTILIZATION OF CAOUTCHOUC OIL.—Danckwerts & Koehler, of Petersburg, prepare this oil by submitting waste India rubber to dry distillation over an open fire, with the aid of superheated steam. A product is thus obtained which, when inspissated and galvanized, possesses in the highest degree the properties of good natural caoutchouc. The lighter oils, which serve for the preparation of varnish, are separated from the heavier ones, which are mixed with hemp or linseed oil, and boiled down. Dupuis, of Paris, proposes to improve goods, dyed in the vat by the application of a dry stove heat, or of steam, or superheated steam. The shade, and sometimes the intensity of the colors is often decidedly modified, though it does not appear in what direction. He prefers hot air for wool, and steam for cotton and other vegetable fibers. The temperature of the air or steam may be from 212° Fahr. to 302° Fahr., and the time of exposure is from half an hour to two hours, or upwards. J. Nathansohn, of Berlin, has patented the following process for coating silk yarns with metals: The yarns, when dyed in the usual manner, are steeped in a cold solution obtained by dissolving half a pound of gelatine in 10 gallons of boiling water. They are next steeped in a similar solution, to which bronze powder of any desired color has been added. After being wrung and dried they are taken through a solution of wax in benzene and dried again.—*Chemical Review*.

TESTS FOR BUTTER BY LIGHT.—A writer in the *Hannoversche Monatsschrift* is even more sanguine than Mylius, who first proposed the examination of butter by polarized light, of the value of his method of testing the purity of butter. Under such light the peculiar crystals come out very distinctly. He has discovered that different fats, like the minerals, produce characteristic marks whereby they can be determined in the polarization colors, and he intends soon to publish plates showing the peculiar forms and colors of each fat, whether raw or melted, or crystallized from glycerine. Mutton tallow gives a blue tone; ox fat, green and white; hog's lard, red and blue, with other colors not so intense; cacao butter, a play of color from the deepest red to the brightest green. Besides being useful as tests of the genuine nature of butter, these optical reactions are said to be available for the detection of foreign fats that may be fraudulently added to chocolate or cocoa.

FOSSIL FOOTPRINTS IN COAL.—At the last meeting of the New York Academy of Natural Sciences, Dr. Joseph Leidy read a letter from Mr. W. Lorenz, chief engineer of the Philadelphia and Reading Railroad Company, referring to a fossil specimen presented to the academy by Mr. William D. H. Mason, of Williamstown, Pa. The specimen is a mass of coal shale with footprints, and was discovered by the donor at the Ellengowan colliery, in the Mahanoy coal field. Mr. Lorenz remarks that it is of special interest as having been the first specimen of the kind found in the anthracite coal field. The specimen is an irregular slab, upwards of a foot long, and less than half the breadth. The upper surface is obscurely ripple marked longitudinally, and is crossed in a slant by seven tracks, which run in pairs, except one, in advance on the right. The four tracks on the right occupy a line of six inches, and are about an inch and a half apart from those on the left. The more perfect impressions exhibit four widely divergent toes, successively increasing in length from within outwardly, excepting that the fourth toe is slightly shorter than the third. The expanse of the tracks is about one inch. The impressions probably pertain to some salamandroid animal; and as it had been found useful to refer to fossil foot tracks as the representatives of the animal by which they were made under distinct names, he would in accordance with a suggestion from Mr. Lorenz, name the form represented by the Ellengowan anthracis.

ESTIMATING METALS IN ORES.—At the late meeting of the Philadelphia Academy of Sciences, Prof. G. A. König exhibited his recently invented "chromometer," an instrument designed for the purpose of making delicate determinations of the presence of certain metals in ores. It is based upon the optical fact that complementary colors extinguish each other if mingled in proper proportions; for instance, if to a green solution a red solution be added, the liquid, if the proper conditions be complied with, will become colorless. Prof. König has applied this principle to the colors which certain metals, as iron, manganese, copper, etc., produce when fused with borax, which is the only chemical used in this method of analysis. He prepares glass or beads containing known quantities of a metal in 100 parts, and observes how thick a glass of one complementary color must be to produce extinction. To accomplish this the instrument is furnished with a glass wedge of a green or red color, cut at an angle of about one degree. By moving this wedge before the glass bead, with the help of a suitable rack movement, a scale moves at the same time, and when the point of the extinction of color is arrived at the reading of the scale refers to a table showing the percentage of metal contained in the examined substance. By this method of analysis a correct determination of manganese in an iron ore can be made in 15 minutes, or copper estimation in 30 minutes.

STEEL IN THE BOILER OF THE FUTURE.—Steel can now be produced by either the "Bessemer" or the "Siemens" process, surpassing in tensile strength and in the power of bending and twisting, for flanging, any best brand iron known, the metal produced by either of these two processes being of a purer and more homogeneous nature than can be made by any of the older methods. The best American boiler plate is said to have a rupturing strain of 70,000 pounds, or 31 tons per square inch of section. The ordinary plate for locomotive boilers is stated to be capable of bearing a strain of 60,000 pounds, or 27 tons per square inch. Steel boiler plates, having very great cohesive properties, have been made in England and in South Wales. It is stated to have a tensile strength of 45 tons per square inch, and to be capable of producing the highest class of steam boilers. As a rule, English boiler plates are of two classes—Yorkshire and Staffordshire; these, however, include the make of other districts. The maximum strength for locomotive boiler plates are as follows: Best Yorkshire iron plates, 25 tons per square inch; best Staffordshire iron plates, 20 tons per square inch; best American iron plates, 31 tons per square inch; ordinary American iron plates, 27 tons per square inch; English steel plates, 40 to 45 tons per square inch.—*Universal Engineer*.

PETROLEUM FUEL FOR STEAMBOATS.—On July 15th, the first known attempt to use petroleum as fuel on board a steamer was tried at Pittsburgh, and the result was very satisfactory. The *Telegraph* says: "The little steamer *Billy Collins*, lay in the Allegheny river this morning with 80 pounds of steam in her boilers, and not a bit of smoke in her stacks, ashes in her pans or clinkers in her fire-box. A few gallons of 63 cent crude oil had run out of a barrel on her guards, and was converted into a waving flame 10 feet long under her boiler, by a little device recently patented." The trip was made a few days ago, and everything passed off satisfactorily. The patent is the invention of a Pittsburgh man.

NEW USE FOR OLD CLOTHES.—A manufactory in Germany turns out 1,000 pounds of grape sugar a day, made from old linen. The old linen, which is pure vegetable fibrine, is treated with sulphuric acid, and converted into dextrine. This is washed with lime water, and then treated with more acid, and almost immediately changes and crystallizes into glucose or grape sugar—which is highly valued in the making of rich preserves and jellies.

The Mining Share Market.

The general features of the share market for the past week has been from a panicky tendency to one of a better feeling. The mines themselves are in a sufficiently good condition to create a better market and more confident feeling, yet owing to the fear of Eastern stockholders, engendered by mistaken ideas propagated through the columns of a respectable Eastern journal, an unloading of stocks began which produced a heavy, gorged effect of the market. This suited the bears and all others who buy short on stock belonging to other people. Some of the brokers offered material aid to wrecking bears. This practice of loaning stocks seems to be very common among brokers, and it becomes a material question whether there is any safety to the owner of the stocks in permitting his stocks to be dabbled with in this manner by a wrecking fraternity. The still condition of the market during the past week, the continual depression of stock in valuable mines has its origin no where else than in the abuse of confidence displayed by this promiscuous manipulation of stock. If a broker loans his customers' stocks, his office should be tabooed at once. A tremendous power over the market is put into his hands, and a power which he does not scruple to use even against his customers' interests. Former panics have been caused by this nefarious practice, and public sentiment required its cessation, but the matter has assumed a gigantic size again, and as the same causes most generally produce the same effects, we may expect a panic more or less disastrous, unless the cause is removed by public sentiment, which even brokers respect. The indications point to a total lack of confidence, and after that will come the deluge. A certain quantity of improvement, however, now exists, and perhaps the better feeling arises from a return of common sense.

The Mechanics' Fair.

Meeting of Members and Appointment of Committees.

The Board of Managers of the Fourteenth Industrial Exhibition met and organized by electing the following officers: Irving M. Scott, President; D. A. McDonald, Vice-President; J. A. Bauer, Treasurer; J. H. Culver, Secretary.

The President appointed the following Committees: Auditing—Columbus Waterhouse, David Kerr, F. A. Frank. Building—James Drury, A. W. Starbird, David Kerr. Circulars and Classifications—Edw. McGrath, A. L. Fish, Nathaniel Hunter. Printing and Advertising—A. W. Starbird, David Kerr, James Drury. Power and Machinery—A. L. Fish, Samuel Dinsmore, S. H. Wheeler. Rules, Regulations and Awards—F. A. Frank, Nathaniel Hunter, J. A. Bauer. Tickets and Admissions—Nathaniel Hunter, F. A. Frank, David Kerr. Music and Decorations—J. A. Bauer, D. A. McDonald, A. W. Starbird. Privileges—Samuel Dinsmore, James Drury, F. A. Frank. Locations—S. H. Wheeler, Samuel Dinsmore, F. A. Frank. Police—D. A. McDonald, C. Waterhouse, Edward McGrath. Horticultural Gardens—J. J. Burns, C. Waterhouse, Samuel Dinsmore. Gas and Water—S. H. Wheeler, James Drury, D. A. McDonald. Art—David Kerr, Edward McGrath, F. A. Frank.

A USEFUL PAMPHLET.—The Pacific Coast Postal Index, compiled by John P. Mains, and published by L. P. McCarty, 604 Commercial street, San Francisco, contains full information concerning postal regulations, rates of postage, and a complete directory of Pacific coast offices. Just the pamphlet needed by all.

MRS. VAN COTT will not preach the gospel for \$3 per day. She lately returned \$36 for 12 days' services, saying the market was an insult to a widow.

OVER 3,000 acres of grass, near Fort Miller, Fresno county, were destroyed by fire last week.

A SEVERE shock of earthquake was felt at Davisville on last Thursday evening.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

ITEMS.—Signal, July 25: Mineral resources of this county are attracting attention. Several rich mines exist. The Colorado mine No. 2 is monthly turning out considerable bullion, which is shipped to Carson mill for collage.

BUTTE.

ITEMS.—Mercury, July 25: The Buena Vista quartz mine is paying well. Jimmy Dancy says he will put up five more stamps right away. Ned Rowe is boss of the mine, and reports a fine five-foot vein, and rich as that. The old 40 and 56 company will put up a mill next year, and prove that old Butte is the best quartz mining county in the State. McSmith passed here from his gravel mine and says it looks "O. K."

CALAVERAS.

ITEMS.—Chronicle, July 26: The claim is supplied with water from a ditch five or six miles in length with a capacity of about 500 inches, and deriving its supply from the river, thus affording a good supply of free water throughout the season. From the time a fair supply of water could be obtained, work has been vigorously prosecuted day and night. A large force has been employed continually and a vast amount of gravel run through. From the ditch the water is conveyed to the claim, a distance of half a mile, across the river under which the pipe is securely laid, and bearing against the gravel bank with a pressure of 100 ft.

EL DORADO.

ITEMS.—Democrat, July 26: The last crosscut of the Kelsey mine showed the ledge to be 12 ft thick, the ore heavily laden with fine sulphurets, and giving assays of \$23.20 to \$28.70 per ton in gold, \$6.55 to \$14.00 in silver. In the Roskranz mine, machinery is being placed and buildings erected.

MONO.

LAKE DISTRICT.—Standard, July 25: The Crescent folks are working night and day, driving a tunnel for the ledge. The rock has been hard, but now is getting softer, finding occasional bunches of quartz. The Silveropolis, one of the most promising locations on the east side of Mineral hill, has a shaft about 23 ft in good ground. They also, are working night and day. We learn from a reliable source of an important strike of a fine body of ore in the crosscut of the Monte Christo mine. The ledge is 12 ft wide and is principally gold quartz.

BODIE MINE.—The middle winze is sunk at a point 80 ft north of the east crosscut, in the north drift. It follows the ledge to where water was struck, about 60 ft, all the way in the richest kind of ore, varying in width from one to three ft. At no point is it richer than in the face at the bottom, where free gold and native silver are seen in abundance. A pump has been put in, and a few feet sunk below the water line, but it is slow work. The ledge in the quiet south of the east crosscut, on the 433 level, is quite flat, the angle being not more than 25°, and the pitch being to the east and north. Ore has been stopped out about 40 ft south and as far up as the point where the ledge becomes perpendicular, a distance of perhaps 60 ft. The face of ore exposed along the south edge of these steps is from 18 inches to two ft of very fine ore, in which free gold can be seen at any point. The same sand, and, as usual, several inches wide, dotted with pink quartz and filled with coarse gold, which has always characterized this vein, can be seen all along the sides of this stop.

NOONDAY.—Bodie News, July 20: The north drift on the 300 level is now in 315 ft, and is being driven as rapidly as possible, with the view of connecting the Noonday mine with the joint shaft. The joint shaft is now down to 215 ft, and is being sunk at the rate of five ft per day. When it reaches the depth of 215 ft, a drift will be run to connect with the north drift on the 200 level of the Noonday; the 212 level of the joint shaft being equal to the 198 or what is called the 200 level of the Noonday shaft. The Miners' mill is kept constantly at work on the Noonday ore.

STANDARD.—News, July 27: The north drift on the 385 level is in 226 ft. They are taking out about four ft of good ore on the footwall. The raise up 230 ft above the drift. During the week a crosscut was run through to the hanging wall, and it was found that the ledge at this point is 12 ft wide of fine ore. In the stop the ledge is about 10 ft wide. The upraise from the north drift on the 550 level is up 42 ft. The ledge here is eight ft wide and fine ore. In the West Standard stop the ledge is 10 ft wide, and of the usual rich ore. In the south drift of the 550 level, the ledge is seven ft wide and of good ore. In the stopes of the Gildea the ledge is three ft wide and looks well.

MARYLAND CON.—The incline is down 370 ft. UNIVERSITY.—The new shaft has attained a depth of 30 ft. The ledge in bottom shows a solid width of three and a half ft of good ore, with indications of an increase in size as sinking progresses; alterations to suit the machinery are all completed, and sinking already resumed.

JUPITER.—Shaft is now down 390 ft, and in the bottom shows a very strong and clearly defined vein of fair ore, which is widening rapidly as depth is attained. The south drift in the Masten-vein is now in 130 ft, the ledge in the face being three ft wide of fair ore. The winze on the Bodie side is down 40 ft, the ledge in the bottom being four ft wide of clean ore.

RED CLOUD.—The west crosscut, 400 level has been advanced during the week 15 ft. The face now in soft, red, rusty porphyry, mixed with clay. Several small feeders of ore have been cut, assaying \$50 and upwards in gold.

TIOGA.—The winze on the 320 level is now down 120 ft. The ledge is five ft wide, of a good quality of ore. In the south drift, on the 380 level, the ledge is three ft wide. The south drift, same level, has advanced during the week 26 ft; the ledge is two and a half ft wide.

GLORY.—The incline is in a ledge three and a half ft wide—bottom of very fine quartz.

MONO.—The joint drift on the 400 level, is in 330 ft, passing through favorable ground. On the 400 level, east drift, have cut four ft of fine-grained quartz, with native silver and vein matter, and expect within 40 ft to cut the rich Bodie vein.

SOUTH BELVIDERE.—Main shaft down 127 ft, bottom in lively quartz; ledge pitching to east.

BOSTON CON.—A strong ledge of good ore shows plainly all the way down the incline.

BOYER.—The shaft, 380 level, is in 119 ft; the ledge is two and a half ft wide, and looking very well. During the week connection was made between the drift and the west crosscut from the 200 level of the Bodie mine. Rock still very hard.

VORTEX.—The ore vein is two and a half ft wide, all good ore, assays averaging over \$100 in gold and silver.

S. NOONDAY.—In the north drift the ledge is 18 inches wide, and of the usual rich ore. Still in porphyry and 12 inches wide, of good milling ore.

S. BULWER.—The ledge is three and a half ft wide of good ore.

NEVADA.

ITEM.—Transcript, July 25: Shoecraft & Sprague, of the Nevada City (formerly Schmidt) mine, have, since taking possession, sunk their incline to a depth of 150 ft, where they commenced to run a crosscut. Within the past two or three days the crosscut has developed a ledge 18 inches thick. The ledge matter is composed of about 80% of very fine sulphurets. It runs north and south, and pitches to the east at an angle of about 30°.

DUNSMIRE PLAT.—The tunnel of the Dunsmire & Davis ledge at Orleans Flat is now in a distance of 320 ft, giving

180 ft backs. The ledge is three ft thick and rich in fine sulphurets and free gold. A crushing of ore will soon be ready. Assays show that it goes \$33.50 per ton.

ITEMS.—Grass Valley Union, July 26: A clean-up of 60 tons of tribute rock from the Alaska mine, made a few days ago, yielded \$1,685, or over \$28 per ton. The machinery for commencing operations on the El Capitan mine, south end of Providence ledge, has been shipped from New York, and will arrive here in two or three weeks. It consists of engine, bolters and hoisting works. At the new shaft of the Rocky Bar mine good milling rock is being raised to the surface, and a crushing of 50 loads of rock therefrom is now going through Sothern's mill.

GODFREY MINING TUNNEL, July 27: Arrangements having been perfected for the running of a tunnel from the Deer creek side of the ridge into Alta hill, through Weid's ranch, the Godfrey mining company have had a survey made and started a hedrock tunnel. The tunnel has been started at a point low enough to drain the gravel channel in the Weid ranch and also the ground of the Godfrey gravel claim. It is expected that gravel will be struck in a distance of 200 ft, although to reach the working of the Godfrey claim 1,000 ft will have to be run.

PLUMAS.

ITEMS.—National, July 26: Immense quantities of black sand containing platinum can be saved from the mines. A new five-stamp quartz mill is to be put up on a ledge opened by Thompson Bros. at Argentine.

SIERRA.

ITEMS.—Dawsonville Messenger, July 26: Most of the mining claims in this section have cleaned up, with returns much greater than were expected early in the Spring.

TUOLUMNE.

TIOGA.—Democrat, July 26: Several parcels of ore from the new mines in Tioga district were sent here this week to parties interested. Some of it resembles in appearance the ore of Bodie. Silver mountain, on which the most prominent mines are situated, is about one mile northwest of Mount Dana. Active operations have been commenced on the Lake, Ahwaga, Revan, High Rock and Atterton. The Ahwaga shaft is down 16 ft in depth, showing ore from the surface. Assays from the bottom of the shaft went \$205.15. At the depth of 50 ft, a crosscut will be run to ascertain the width of the ledge. The shaft in the Lake mine was down 14 ft, and the vein runs from 35 to 40 ft in width; it may go to 50 ft, as they have not found the full width. The rock assays rich, specimens of which can be seen at Adam Haag's store. The ledge has been traced for several miles. Some 30 claims are already located, each 1,500 ft in length.

TULARE.

GENERAL ITEMS.—Miners are prospecting for placer gold on King's river, Tulare county, at the mouth of Sycamore creek, in the vicinity of old "Sycamore gulch diggings," with fair results. Years ago these rich claims were worked out, so far as practicable, but the volume of water in the river prevented further development.

NEVADA.

WASHOE DISTRICT.

UNION CON.—Gold Hill News, July 30: On the 1000 level the drift east toward the Union shaft is making a foot and a half per day, through soft ground carrying some water and streaks of clay; total length from the north lateral drift, 134 ft.

ORION.—The north drift, 2300 level, is averaging three ft per day through vein matter showing streaks of quartz; total length, 42 ft. The joint Mexican winze from the 2100 level is now down 20 ft and cutting blasting porphyry.

BELCHER.—The mine is cooling off since the connection north with the Crown Point on the 2700 level.

JUPITER.—Crosscut No. 1 west, 1500 level, is nearing the ore channel rapidly. The formation strengthens as it is penetrated.

ALTA.—The crosscut in Benton ground, 140 ft north of the incline, is in 40 ft and is cutting a very fine formation of vein material carrying bunches and stringers of ore. On the 1500 level, the drift north, along the vein in Lady Washington ground, shows a ledge of clay and bunches of low-grade ore. In a day or two ore will be regularly stopped from the 1450 up to the 1350 level, and the mill will be kept in constant operation.

CALIFORNIA.—The joint west crosscut, 850 level, is adding an average of five ft per day to its length, and is cutting blasting porphyry. On the 1950 level a winze from the north end of the ledge has been started on down, and has passed through ore of low grade to a depth of 15 ft. A crosscut is about to be started west on the 2150 level, and will be run to a point under the north ore body, as developed on the 1750 level, to explore the ground there.

CON. VIRGINIA.—Last evening 12 bars of hulkon were shipped, aggregating \$47,373.97. The west joint crosscut on the 850 level is being rapidly advanced through vein porphyry; total, 523 ft. On the 1500 level, and from the face of the drift running west of the old stopes, a raise has been started, which is now up 13 ft, and shows ore of low grade.

SAVAGE.—The 2100 level has been drained and the water is being gradually lowered toward the 2200 level. The large pumps are throwing their full measure of water into the Suro tunnel, and the water is being carried off by sending water to the Combination shaft, where it is raised to the tunnel level and discharged. The south winze from the 2100 to the 2200 level is being repaired to aid in ventilating the 2200 level when it is reached.

JULIA CON.—The flow of hot water recently encountered in the face of the crosscut, 2000 level, has greatly decreased and is nearly entirely stopped by the pumps.

SARGE, NEVADA.—The air currents which were disarranged by the connection with the Union shaft on the 2000 level are becoming somewhat settled, and ventilation on the disturbed levels is improving gradually.

YELLOW JACKET.—Last Monday evening the sills for the 2700 station were laid in the new shaft.

OVERMAN.—The east crosscut from the north lateral drift, 1200 level, is being rapidly advanced through vein porphyry. The south vertical winze from this level has reached a depth of 303 ft, and a sump is being made.

EXCHEQUER.—The air pipes for blowers and compressed air are all ready for use, but the heat has hindered operations.

LADY FRANK.—The drifts north and south, on the 600 level, are looking up noticeably and the bottom is cutting a formation of black sulphurets ore have lately been encountered. The crosscuts east from these two drifts are cutting some fine-looking quartz. The crosscut west, 750 level, is in hard rock. The east, same level, is finding some promising quartz, but as yet of low grade.

CON. IMPERIAL.—The north drift, 2600 level, is making an average of four ft per day, and is now in 524 ft, the face in hard porphyry, with stringers of quartz which assay fairly.

HALE & NORRIS.—Water stands 22 ft below the 2100 level.

TROJAN.—The northeast drift, third level, is passing through quartz and porphyry. The raise from the east crosscut, same level, is also in quartz and porphyry, the quartz assaying 100% in gold. The drift is down 1200 level in porphyry; total length of west drift, 85 ft.

SUTRO TUNNEL.—The heat prevents work in the south branch at present. A corps of workmen are engaged in placing the sub-drain in where the boxes were raised for temporary use.

WARD.—The shaft has reached a depth of 1,575 ft and is encountering a heavy flow of water. The bottom is cutting a formation of Bird's-eye porphyry.

BULLION.—The winze has now attained a depth of 65 ft on the slope below the 2150 level, the bottom in a mixture of clay and porphyry.

LEVIATHAN.—A little more quartz is coming in. Around in the face of the north lateral drift is hard blasting porphyry.

GOULD & CERRY.—Sinking the joint shaft is slow, on account of the heavy flow of water. The work of putting in

the foundation for the pumping engine has been commenced and is making favorable progress.

NORTH BONANZA AND FLOWERY.—The north and south drifts, 400 level, are making good progress along the vein, and sinking is going on as usual. The north drift, 300 level, is in vein matter carrying stringers and bunches of ore.

VIROBIA, Enterprise, July 25: The late connection with the Union shaft, on the 2000 level, was an event of great importance to all the mines lying to the northward of the C and C shaft. The drift which thus connected with the shaft is 2,500 ft in length, of extra light and width. It is the channel through which flows an immense current of pure and cool air—a great life-giving river pouring along 2,000 ft below the surface of the earth. It creates a new surface, as regards air, at the great depth of 2,000 ft below the surface of the earth proper. The air, which was hot and terribly foul when the connection was first made, is now as pure as that which sweeps over the surface of the earth.

BELMONT DISTRICT.

BEAUMONT.—Courier, July 25: The raise from 300 level was advanced since last report 14 ft in a fine vein of quartz, averaging four ft in thickness and from eight to twelve laches of good milling ore. In our 200 south level there is opening up a nice body of high-grade chloride ore 100 ft south of shaft and 40 ft above the level. Drift running north under the vein from crosscut in 400 level was advanced 19 ft. The drift south has been started on the vein from the long crosscut in 400 level and finds the quartz very soft, and carrying a strong trace of mineral.

ALEXANDER.—There is a vast amount of ore in sight, enough to keep the mill running for years to come. The bullion shipments from this mine are regular and leave a handsome margin for profit after paying all working and other expenses.

ESMERALDA DISTRICT.

RICH STRIKE.—Herald, July 26: A rich and valuable discovery has been made inside the limits of Esmeralda mining district, which, when made public, will surprise this most sanguine, and open the eyes of those who have always known it was there. The find consists of a gold ledge as near as can be ascertained about 10 ft in width, and as far as discovered 1,000 ft and more in length. It is what is called a blind ledge; and is equal in richness to the best find in Bodie, or the glittering chambers of Del Monte.

ARIZONA.

GLOBE.—Silver Belt, July 25: Work on the La Plata is being pushed; the vein matter is looking better as developed. Brewster is working his mine, the Dundee, which is situated on the west end of the Basin. It shows a very good vein of chloride and horn silver. The Mack Morris mine produces rich ore. Ore is now being taken from the new shaft on the west end of the claim, which assays from \$3 to \$6 per pound. Dr. Thatcher, at the depth of 95 ft in the shaft of the S. W. Alice mine, came into an ore body of black spar. Many pieces of the rock are covered with beautiful crystals of horn silver. The vein is well defined and is increasing rapidly in size.

PRESTON.—Preston Miner, July 25: Eighteen bars of bullion from the Agua Fria smelter came in this morning to F. W. Blake, belonging to the Peck mining company, weighing 1,561 pounds. This bullion has been made by Mr. Syme at the Agua Fria from galena ore found in the Peck mine, which contained too much lead to mill closely. Rich placer discoveries have lately been made on Lynx creek, Walker district, and claims there pay \$10 per day to the land.

TUCSON ITEMS.—From Clifton, Dos Cabezas, Chiricahua and Swishish districts come reports of extensive and rich mineral deposits. At Dos Cabezas, and southward to Bowie, the ledges are large and very rich. One vein bearing gold is continuously located for nine miles. It lies between perpendicular slate walls, and the "Bear Cave" claim of 1,500 ft is one containing gold in every place where the bedrock is exposed. The ore is of a fine grade, along the Fresno river which are from 10 to 150 ft deep, and all the dirt will pay. A number of miners are taking out \$20 per day to the hand. In the same neighborhood are numerous large veins of quartz-bearing gold.

MARICOPA.—Phoenix Herald, July 19: In the Tonto district the Mazatzal company's mill will resume crushing as soon as the rain falls in sufficient quantity to supply it with water. The Al Seiber & Co. have cut 50 ft of ore, Bonanza, and find the ledge carrying considerable quantities of free gold. The House and Rouse mines are looking extremely well, the main ledge having been found in the tunnel which cuts it at a depth of about 125 ft. The Mauniks & Stroud mine is being gradually developed as the weather permits. Every indication of permanency is to be seen in this mine. The ledge is about eight ft in width.

COLORADO.

SILVER CLIFF.—Prospector, July 25: A few days ago the miners on the Wolftown ledge struck a three-inch streak of sulphurets which runs very high. A new find has been made six miles east of town. The float on the ground assayed 300 ounces. A "blow-out" has been found east of the city four miles in the footwall of the ledge, an extremely fine-looking quartz. The ledge has been named the Sunset. A large strike was made in gray copper and silver. A very handsome piece of gold-bearing rock was found near the surface yesterday, six miles east of town, by Francis Franse near the saw mill.

ITEMS.—Georgetown Miner, July 19: In Baker gulch, Rabbit-range, some party struck, near the grass roots, ore consisting of solid rules of silver and lead, assaying as high as 17,000 ounces per ton. Parties leasing on the Rogers ledge, Democrat mountain, have, after working nine months on lean ground, struck it rich. We saw a specimen yesterday filled with native silver. Specimen assays from 1,100 to 3,000 ounces. Mill runs 810 ounces per ton. A new strike is said to have been made at Geneva gulch. It assays over 3,000 ounces, is nearly two ft thick, and is called the Wolf. The ore is sulphurets of bismuth. The prospects about Geneva are first-rate.

SILVER CLIFF.—Denver Tribune, July 23: On the Powhattan a fine fissure vein was uncovered, the mineral at grass roots assaying from \$30 to \$51 per ton. A tunnel has been run into the mountain 65 ft, which with 40 ft more dead work, will cut the vein 75 ft below the surface. The Domingo also has a true fissure vein, which at a depth of 25 ft shows argentiferous galena and gray copper, carrying from 71 to 310 ounces silver, and 3,410 ounces gold. The Wanderer, another new strike near the Ben Franklin, has a large body of mineral at a distance of 50 ft, which runs 200 ounces silver. On the Denver ledge, adjoining the Lone Star and Gray Eagle, where Captain De LaMar's diamond drill is now at work, it is reported that mineral carrying about four ounces gold has been found. The Round Mountain tunnel company are working two shafts, and the Iron Mountain company are pushing their way into the hill with three shifts of men, still on drift No. 1, which is now in 75 ft from foot of shaft. The Rambler, Lone Star, Hunabolt, Abandoned, Lady Franklin, Rocky Mountain, New El Dorado, and Leavenworth & Zebra and Wild Cat are all working two or three shifts surfacing ore, and the output is more than satisfactory. From the last named the owners have on their dump about 100 tons of mineral, for which they are offered \$80 per ton, and as yet their shaft is down but 70 ft. The Buckeye company are now working 30 men on the King of the Valley and Gray Eagle. Drift No. 4 on the Thomas Jackson, and the Diamond drill is now at work. It is reported that the latter runs about 600 ounces.

CHISTEN COUNTY.—Prospector, July 24: The Mississippi ledge has struck a rich deposit of carbonates. The Rocky Mountain ledge, adjoining the above named, is showing some very rich truck. The Crow Butte ledge, an extension of the Lady Franklin, belonging to Thomas Jackson, William Sanders and William Craig, at a depth of seven ft gives an assay of 22 ounces in silver and 8% copper. The Lady Franklin ledge is growing richer as it goes down. There are now 10 tons of ore on the dump ready for the mill, which will average 175 ounces, while the shaft shows

[CONTINUED ON PAGE 76.]

Notes on the Fishes of the Pacific Coast.—No. 1.

At the last meeting of the California Academy of Sciences a paper was read by W. N. Lockington on new and rare fishes of the Pacific coast. We shall print these notes in sections as space will allow.

I have lately been occupied in studying the flat-fishes or Pleuronectidae of this coast. Since the date of my last paper on the subject, I have been fortunate enough to find another new species, and also to verify the occurrence in our markets of a species of a halibut (*Hippoglossus*), which is probably identical with the European species. It will be as well, therefore, to commence the present paper by recording some additional information respecting this group of fishes. Prof. Theo. Gill, of the Smithsonian Institute, writing in 1864, enumerates 16 species of Pleuronectidae from the Pacific coast of North America. Not that Prof. Gill had seen all these species; the list was a literary enumeration of species described by various authors. Among them were two species described by the old Russian naturalist, Pallas, and inhabiting the seas between Kamtschatka and North America. These two species have not yet been, with certainty, identified, and, as descriptions of that date were very short, giving but few characters of the animal described, it is not unlikely that one or both of them may be identical with species now known under other names. Two of the species enumerated were characterized by Dr. Gunther, of the British Museum; two or three by Dr. W. O. Ayres, formerly of this city, and one by Prof. Gill himself. Most of the others had been described by Girard in the "Pac. Rail. Rep.," vol. X.; but one of these, the common flounder, with rough scales and striped fins, had been proved by Dr. Gunther to have been first noticed by Pallas. In the following year, Prof. Gill added another species to the list, making 17 in all. I am thus particular in giving the number because I wish to prove to you this evening how it is that, although I have found three new forms, the distinctness of which I could prove in five minutes to the satisfaction of any person who would take the trouble to look at them, I am yet in a position to confidently assert that the distinct species yet known on this coast are fewer than 17, the number to be found in Prof. Gill's memoirs. Let us begin by leaving out the two unidentified and perhaps more northern forms described by Pallas, and the northern *Pleuronectes glacialis*, of Richardson. We ought then to have 14 species upon this part of the coast, without counting the three I have lately found. But there are really only ten species, excluding the three just found. It may not be amiss to show how these "nominal" species were made, especially as in so doing it will be made evident that the most learned and acute men, working from a few specimens preserved in alcohol, or, worse still, dried or skinned, may fall into errors which those who describe from quite fresh specimens are not likely to fall into. Girard's descriptions were incomplete and too often taken from young, immature specimens, or from a single specimen. From this insufficiency of the descriptions of Girard it came about that Gunther and Gill, from specimens forwarded to them, redescribed the same fishes that were described by Girard as so many new species, not recognizing the identity of their specimens with Girard's.

One of our common flounders was thus made into three species, for one of which Dr. Gunther is responsible, for the other, Prof. Gill. The latter authority doubted the former's species, but added another, describing it in terms which are but a better description than Girard's, of Girard's species. Our "Turbot" was so indistinctly characterized by Girard that when Dr. Gunther received several specimens of it, he thought it another species, and placed it in another genus. Prof. Gill doubted the distinctness of the two, but in the absence of material, could not prove their identity. These errors were all of a nature which no naturalist, unless he have before him a series of fresh specimens, can avoid falling into; but so much cannot be said for another of Gill's species, founded on a sun-dried specimen of a flounder sent him by Dr. J. G. Cooper, from San Diego. The description of this fish, a very full and complete one, most unmistakably applies to a form very common in our markets, and first described, but incompletely, by Girard. The character on which Prof. Gill's new species and genus were founded are simply those due to the rough way in which the fish was preserved, and I cannot but wonder that Prof. Gill did not perceive the identity of his specimen with Girard's species.

Again, I have lately been able to prove that one of the species described by Dr. Ayres, viz: *Hippoglossus californicus*, the California or Monterey halibut, is identical with a species previously described by Girard. Girard's name, *Paralichthys maculosus*, has precedence of Ayres' name, and must be retained as the scientific name of the species.

I will now give a few notes upon the species of Pleuronectidae not mentioned in my last paper.

Hippoglossus vulgaris.—A true halibut, very nearly related to, and possibly identical with, the halibut of the Atlantic, is occasionally brought to this market, but as yet I have only seen one specimen, or rather part of one, since the central portion had been sold away before I saw it. Its rarity may be inferred from its

price, which was 50 cents per pound, but I am told that as the season advances it may probably become more abundant. The first to bring the occurrence of this fish on our coast to the notice of naturalists was our Dr. Ayres. (Proc. Cal. Ac. Sci., vol. I, p. 40, 1855). "Another species, in which the eye is on the right side, is occasionally taken near the Farallones, opposite the mouth of the bay, which I do not feel warranted in separating from *H. vulgaris*, without direct comparison." Fin-rays, D. 102, H. 73, p. 16, v. 6.

Dr. Ayres, though he suspects the identity of this fish with the European form, does not prove it; and as this point has never been proved, I am most anxious to procure a specimen for this Museum, so that it can be examined at leisure, and its characters compared with the European form.

The only notes I could take were as follows: Eyes far apart, the distance between them equalling or exceeding their longitudinal diameter; teeth numerous, in a double row along both sides of both jaws, with some irregular teeth not in the exact line of the rows, but between them; branchios tegals (the bones supporting the gill-membrane) seven in number. About twenty caudal rays, the principal ones several times bifurcate, posterior margin nearly straight.

The specimen weighed between 40 and 50 pounds, but this fish attains a far greater size and weight. It is said to be common upon the more northern parts of our coast, also on the coast of British Columbia and Vancouver's island.

Note.—Since writing the above, I have been informed that Prof. B. Goode, of the Smithsonian Institute, says that the Alaska halibut is identical with the European form.

About June 12th, a schooner load of this species, brought, packed in ice, from Vancouver's island, for once glutted the market with halibut. One of these fishes that I measured was 5 feet 11 inches in total length, and one weighed 220 pounds.

Glyptocephalus zachirus. Nov. sp.—This species is remarkable for the great length of the pectoral fin of the right or colored side of the body. This fin is longer than the head and about equal to one-fourth of the total length of the fish, but only the central rays are thus lengthened, the others decreasing rapidly on each side. This long pectoral, together with the blunt shape of the front part of the head, sufficiently distinguish it from its congener, *G. pacificus*, and from all our other flat-fishes. It is of a uniform grayish color, formed by black points on a brownish ground. The blind side is beset with dark points on a white ground, as is the case with *G. pacificus*. The first of the season were in the market March 21st, and since then it has been of tolerably regular occurrence, but not abundant. It does not appear to be taken in the Bay. The largest I have seen was a little more than 14½ inches long, but only 4½ deep, so that, for a flat-fish, it is very slender. In flavor it excels most of the other Pleuronectidae of this locality.

The species of *Glyptocephalus* mentioned in my last paper (*G. pacificus*) has not been of uncommon occurrence during the last few weeks among the heaps of small flat fishes exposed for sale in the Clay-street market. The largest I have yet seen measured only 11½ inches in length, and I am rather inclined to think that it does not attain much larger dimensions. In flavor I believe this fish to be inferior to its congener.

The curious "Bestard Turbot," as the dealers call it (*Pleuronichthys canosus*), has been rather common lately. It is believed by many of the dealers to be, as the name they give it imports, a cross between a turbot and some other species; but of course this idea is inadmissible.

Leaving the Pleuronectidae, I will now give a few notes upon other species.

Stereolepis gigas, Ayres, Jew Fish.—This large species was supposed by its describer to be seldom found to the northward of Point Conception, which is about 40 miles west of Santa Barbara.

The individuals upon which his description was founded were taken in San Francisco bay, but their rarity here, together with the fact that many other southern species appear to make that point their northern limit, induced him to consider as stragglers, all specimens taken to the north of it.

It appears, however, that the Jew fish, though not very common, is regularly taken in the neighborhood of Monterey and Santa Cruz, so that Monterey bay must be included in its normal range. During the present summer I have seen three small specimens (about two feet long) which were taken in Monterey bay. These individuals give no idea of the size attained by the species. The two caught in our bay weighed, as stated by Dr. Ayres, 187 and 300 pounds, and measured 5 feet 8 inches and 7 feet in length respectively; Messrs. Spence and Johnson received last year from Monterey an individual weighing 412 pounds; and one as large, or even larger, was sold in Clay Street market. Mr. Johnson and the dealer in Clay-Street market both assure me that the fish is excellent when cooked; yet buyers do not appear to take to it, on account of its decided ugliness. It is stated to be of sluggish habits, and to live in deep water hidden among the rocks.

This fish belongs to the *Serranidae* or marine *Percide*. It is a stout, deep fish, its greatest depth equal to nearly a third of its total length; the head is large, equal to a quarter of the total

length; and there are two dorsal fins, the first large with nine stout spines; the second shorter but rather higher with three spines and eight soft rays. The scales are small; and the teeth very numerous and small.

Anoplopoma fimbria (Pallas), Ayres, Candle-fish.—This species is very rare in the markets of San Francisco, but appears to have been more abundant this year than at any previous period.

Dr. W. O. Ayres (Proc. Cal. Acad., 1859) states that in his time stragglers only occurred in the markets; and the fish-mongers call it a "new" fish, and declare they have never seen it before. Dr. Ayres gives the number of rays in the first dorsal as 23, but I can only find 21 in the specimens I have examined. Probably the number varies slightly. The outline figure in the Proc. Cal. Ac. vol. I, 1859, shows 22. The tail is much more deeply emarginate than is shown in the figure, as the central rays are only about half as long as the outer ones. Most of the individuals brought to the markets are not over ten inches in length, but Dr. Ayres states that he saw one that measured eighteen inches. A specimen procured in May for the Cal. Acad. Sci. measures twelve inches in length. The fishermen call this species candle-fish, but whether on account of its oiliness, of its length and slenderness, or of a fancied resemblance to the species called candle-fish in Oregon and northward I cannot tell. The last-named candle-fish (*Ammodytes personatus*, Grd.) is not at all nearly related to the present species; it is so oily that it is said that the Indians make their candles by pulling their yarn through its flesh. Between October and May *A. fimbria* did not occur in the markets, but it is not unlikely that the severe weather which prevented the fishermen from trawling was the cause of this.

This species was described by Dr. Ayres (Proc. Cal. Ac. Sci., 11, 27, 1859) under the name of *Anoplopoma merlangus*; but Dr. Steindachner identifies it with a species described by the old Russian naturalist, Pallas. In color it is plain greenish brown, becoming lighter beneath; the fins colored like the body. Traces of lighter blotches may be observed on the sides of some fresh specimens. The body is long and slender; the scales small and ciliated; the teeth small and numerous; and there are two dorsals, distinct and remote from each other, a character by which it may readily be known from the other Chiroids. Dr. Ayres was puzzled to tell whether its affinities were with *Percide*, *Chiroide* or even with the Gadoid or cod-fish tribe, to which it has a general resemblance. Dr. Gill, however, classes it, with the Chiroids.

Probably San Francisco lies very near the southern limit of the range of this species, which becomes more abundant northwards, and is found along the northern coast of Eastern Asiatic Russia.

Chitonotus megacephalus, Nov. sp.—Three individuals of this species are all that I have as yet seen, and one of these was picked out from a heap of prawns (*Pandalus danae*), crustaceans which are trawled from rather deep water. I conjecture that its rarity may be accounted for by its habitat and by its small size, which does not tempt the fishermen to procure it. Those which came to market are accidentally taken while trawling for prawns. It is a very singular little fish. The head is immense in comparison with the rest of the fish, occupying nearly a third of the total length, tail-fin included; and the mouth is half as long as the head. The eyes, close together on the top of the head, are very large, nearly one-third of the length of the head, and between one-tenth and one-eleventh of the total length of the fish. The first or spinous dorsal is divided into two portions, the first containing three, the second ten spines. The first spine is almost as long as the head, but the third is shorter than the anterior spines of the second portion of the spinous dorsal. But the greatest peculiarity of the fish is in the scales, which are entirely confined to the upper part of the body, leaving the lower undefended. Each scale is ctenoid or spinous on its posterior margin, and along the lateral line runs a row of larger scales set with spines on both their upper and hinder margins. The head has sundry spines by way of defence, the largest being a compound four-pointed affair on the upper angle of the preoperculum. The total length of the fish is about five inches, its color olivaceous, becoming whitish below.

Caulolatilus princeps.—This has been one of the most puzzling of the marine fishes of this coast, and the puzzle, which consists in ascertaining whether there are one or two, or three species of the genus *Caulolatilus* on the Pacific coast, is not yet solved. *C. princeps* was first described by Jenyns, an English naturalist, from the Galapagos islands, a little south of the equator, and opposite the coast of Peru.

In the Proc. Cal. Ac. Sci., vol. III., Dr. Cooper described, under the name of *Dekaya anomala*, a species which was afterwards ascertained by Prof. Gill to belong to his genus *Caulolatilus*. Dr. Cooper's specimen was from Santa Catalina island, where the species is known as "White-fish." Finally, Prof. Gill described a *C. affinis*, from a small specimen (three feet long) obtained at Cape St. Lucas. The example described under these various names differed considerably in shape, fin-rays and color, and the localities, as will be seen, were so far apart that, as the examples did not agree, it was natural to suppose them separate species. We have lately obtained two individuals in the markets of San Francisco, both probably brought from near Monterey; one is an adult, 17½ inches long, the other, half-grown, and 10 inches long. The

first is very deep in front, owing to the development of fat upon the back of the head and anterior dorsal region; thus approaching Jenyns' form; while the second resembles Cooper's specimen, and has a black spot above the pectoral fins, as in Gill's *affinis*. The difference between these two specimens, both from the same locality, and that a locality from which the fish has not previously been recorded, leads me to believe it probable that there is in the Pacific only one species of the genus *Caulolatilus*, with a known range extending from the Galapagos to near San Francisco, and probably a further extension southward. This is the only species of its family that occurs on this part of the coast. The scales are ctenoid, as in the perch tribe, but very small; the preoperculum set with small teeth on its edge; the dorsal and anal fine very long, the soft portion of the former much more developed than the spinous portion.

Platinum.

The inquiries of Mr. Edison concerning platinum have excited a desire for investigation that can only be satisfied by supplying the demand, if demand exists. We say if the demand exists, because it is not at all certain that a market for platinum would justify the practical abandonment of hydraulic gold. If the desirability of the electric light should be practically demonstrated and that light take its place among the utilities of present civilization, then perhaps a sufficient demand would be created to develop our platinum deposits. Heretofore miners have paid no attention to this metal, allowing it to go to waste in quantities together with the osmium and iridium, with which it is associated. All of our hydraulic mines could save a certain quantity of platinum, as that species of mining is generally confined to cement beds and alluvial deposits where platinum abounds. It is found in large quantities in the black sand, known to every hydraulic miner, and exists in small thin scales. The platinum product of the world hardly exceeds, at the present time, 1,000 pounds per annum, and commands a comparatively low price—probably not more than \$2 per ounce—hence the lack of desire to mine for platinum and abandon so precious a metal as gold. The expense of mining it would be about the same as gold, the demand, though very large, would not entice many from the yellow metal. Upon the northern coast of California a mixture of gold and platinum metals, in extremely small scales, is washed from the beach sand and separated by amalgamation, platinum and mercury not having any affinity. It is also found like gold in alluvial deposits, in rounded grains or nuggets, nearly always associated with osmium and iridium. Observations of the rocks and minerals found with platinum in deposits lead to the belief that it is chiefly derived from the disintegration of serpentine rock. Chromic iron is a common associate. It is also found in syenite. It has never been found in regular veins in quartz. If Mr. Edison can show that quantities of platinum are needed, it will pay the hydraulic miners to save it for him, which they can easily do to the full extent of the demand.

RELATIONS OF FUSION TO MOLECULAR OSCILLATION.—R. Pictet supposes that the temperature may be represented by the length of the calorific oscillation of the molecules of a body, and from this hypothesis he deduces the two following laws: 1. The higher the melting point of a solid the shorter are the molecular oscillations. 2. The products of the temperatures of fusion by the lengths of oscillation are constant for all solids. The laws are confirmed by all the metals of which the coefficients of dilation have been determined with sufficient accuracy. Similar relations hold good for the elements of volatile liquids, when they are compared at their boiling points. These laws may be classed with the law of constancy between the products of atomic weights and specific heats.—*Comptes Rendus*.

PALMETTO FIBER FOR PAPER.—The Fernandina (Fla.) Mirror reports that the machinery, lately brought to that place by Prof. Loomis, for the preparation of palmetto fiber is working satisfactorily, and that the experiment is an assured success. The stalks of the scrub palmetto are used. It is said that the fiber is likely to prove useful for cordage, paper, tubs, pails, flour barrels, boats, powder kegs, and no end of other articles of general use. A portion of the fiber shipped to paper mills is intended for the manufacture of high-grade paper to be used by the Canadian Government in the printing of bank notes. Ultimately, it is said, the various grades of paper fiber will be made into pulp in Florida.

THE MISSISSIPPI JETTIES FINISHED.—Capt. J. B. Eads reports, under date of July 10th, that the greatest depth and width of channel required by the Jetty Act at the mouth, and also at the head of South Pass, has been secured. The completion of the great work was certified to the Secretary of War the same day by Capt. M. R. Brown, of the United States Engineers, inspector of the work. The jetty channel is over 30 feet deep, and a good navigable channel of 26 feet, measured at the lowest stage of the river, exists at the head of the passes. The benefits to commerce likely to flow from this brilliant achievement are inestimable.

THE ENGINEER.

The New York and Brooklyn Bridge.

At a meeting of the Trustees of the New York and Brooklyn bridge, July 7th, the contract for supplying the steel and iron for the suspended superstructure, was awarded to the Edgemoor Iron Co. The contract calls for 10,728,000 pounds of steel and 34,000 pounds of iron. The bid of the Edgemoor Iron Co. was 4 35-100 cents a pound, amounting to \$463,147. Chief Engineer Roebling said that when the change from iron to steel was first contemplated he supposed that the difference in price would be at least \$100,000, but in fact the lowest bid for steel exceeded by only \$4,000 the accepted bid for iron last year. The difference between the lowest bid and the lowest bid for crucible steel was \$364,000.

Both towers of the bridge have been completed, the last work on the Brooklyn tower having been finished July 5th. Mr. Kingsley expressed the belief that through this contract it would be possible to complete the bridge by January 1st, 1881. The financial condition of the bridge on June 30th was as follows: Total receipts, \$10,623,492.94; total expenditures, \$10,523,374.88; outstanding liabilities, \$112,807.62.

ROCKING PIERS FOR VIADUCTS.—A novel construction has been employed in the Dysdale viaduct on the railroad from Christiania and Fredrikshald, carrying a single rail over the Dyse rivulet in Norway, in the shape of rocking piers, the object of which is to protect the structure from the effects of expansion and contraction due to alterations of temperature. The piers which support the superstructure are of wrought-iron with a lattice-work web. In the longitudinal direction of the viaduct, which is 603 feet in length, there is only a single column between each span, possessing no stability in itself, and the upper end of this column is allowed to move along with the superstructure when the latter expands and contracts. The lower end of each pier rests on a hinged shoe, so that breaking strains are avoided, and the load is always rendered central to the pier columns. The movement of the iron-work in a longitudinal direction is transferred to the one abutment, on which are the necessary bed-plates provided with rollers; on the other abutment the superstructure is kept in place by a fixed shoe. With this arrangement no special expansion-joint in the rails is necessary, as the sleepers and platforms are quite independent of the expansion and contraction of the ironwork.

HIGHWAY CROSSINGS.—The question of highway crossings over railroads at grade is getting to be a serious one in many of the suburban towns about New York, and particular attention has been called to it just now by the killing of a wealthy old gentleman by a train on the Harlem road at Morrisania, a short time ago. *Punch* once said that it would be necessary to kill a bishop in order to call attention to some dangers of railroad travel, but in this case a millionaire will probably be sufficient. Already the papers are full of letters and editorials on the subject, and all sorts of suggestions are made for a remedy. Within 15 miles of New York there are many towns and large villages with a considerable traffic on their streets, and all of them have grade crossings at points where trains are frequent and the danger great. There is generally a strong objection to gates at crossings on account of the delay caused by them, but it is a question whether people will not have to submit to that, as the risks now run are too great to be endured much longer. — *Railroad Gazette*.

BRIDGE GUARDS.—The New York, Lake Erie & Western Company is putting up guards at all its overhead bridges, to warn brakemen of their approach. The guards are made by putting up, some 300 feet from the bridge, posts on each side of the track, to which cross-pieces are attached, from which hang a number of pieces of rope so that, no matter which way a brakeman is looking, if he is standing so that his head will strike the bridge, the harmless contact with the dangling rope ends will warn him of his danger in time to avoid it. The New York Central, we believe, uses a similar device. The Pennsylvania and some other companies use a slender rod hinged to a post at the side of the track, with a spring to keep it up to its place. This will strike a brakeman a sharp rap, and swing back to its place when he is past.

A FEAT IN ENGINEERING.—Owing to the immense weight that they sustain, the iron shoes in which rest two of the spans of the railroad bridge at Easton, Pa., lately sunk about an inch, throwing the bridge out of grade. As it was certain that the depression would continue, from the fact that the inside masonry of the pier is less solid than the outside, an iron casting, weighing 7,000 pounds, was recently successfully placed under the spans, in order to elevate them. The spans weigh 180 tons each. Hydraulic jacks were used. The spans were raised, the masonry redressed, the castings placed in position, and the spans lowered without the stoppage of a single train.

The Aztlán quartz mill, 10 stamps, six miles south of Prescott, Arizona, was totally destroyed by fire on the night of the 18th inst. Supposed to be the work of an incendiary. Loss, \$12,000.

USEFUL INFORMATION.

Distinguishing Butter from Lard, Beef Fats, etc.

Mr. William Gustavus Crook, public analyst for Norwich, England, describes a method which will in a few minutes distinguish butter from the fat of beef, mutton, or pork, or mixtures of them.

The sample to be examined (if in the form of butter) must be first melted and rendered pretty free from water and salt, by filtration if necessary; 10 grains are then to be put into a test tube and liquified by placing the tube in hot water at about 150° Fahr.; remove the tube when ready, and add 30 minims of carbolic acid (Calvert's No. 2 acid, in crystals, one pound; distilled water, two fluid ounces). Shake the mixture, and again place it in the water bath until it is transparent. Set the tube aside for a time. If the sample thus treated be pure butter, a perfect solution will be the result; if beef, mutton, or pork fat, the mixture will resolve itself into two solutions of different densities, with a clear line of demarcation; the denser of the two solutions, if beef fat, will occupy about 49.7%; lard, 49.6%; mutton, 44% of the entire volume; when sufficiently cooled, more or less deposit will be observed in the uppermost solution. If olive oil be thus tested, the substratum will occupy about 50%; with castor oil, there is no separation. With some solid fats (not likely to be used fraudulently) no separation whatever takes place; the addition of a minute portion of alkali root will render the reading of the scale extremely distinct by artificial light. The author states that the above method (although not intended to surpass other processes) is capable of wide application, the saving of a large amount of time, and the reliability of its results will at once recommend it as a "first step" in butter analysis.

CEMENT FLOORS FOR CELLARS.—For making floors, the following method is said to produce very desirable results: Four parts coarse gravel, or broken stone and sand, and one part each of lime and cement, are mixed in a shallow box, and well shoveled over from end to end. The sand, gravel and cement are mixed together dry. The lime is slaked separately and mixed with just mortar enough to cement it well together. Six or eight inches of the mixture is then put on the bottom, and when well set another coating is put on, consisting of one part cement and two of sand. This will answer for making the bottom of a cistern that is to be cemented up directly upon the ground without a lining of bricks. This will also form a very good cellar floor. A cement of one part sand, two parts ashes and three parts clay, mixed with oil, makes a very hard and durable substance like stone, and is said to resist the weather almost like marble.

LIGHTNING RODS NOT INSULATED.—Insulators should not be used in putting up lightning rods on buildings for protection against the electric current. The rod should be fastened directly against the building. But the most important precaution is to make sure that the bottom end of the rod has a large conducting surface in contact with the earth. Better have no rod than simply to stick the end a few feet down into dry earth; the proper way is to solder the bottom end of the rod to a metal water pipe or gas pipe in the ground. If there are no pipes, then make a long trench and put in some good conducting material, such as fine charcoal, or hard coal dust, iron ore, or old iron, making a good connection between the bottom end of the rod and this conducting material.

THE USE OF FILES.—A new file should always be used with a light pressure until the very thin sharp edges of the teeth are worn off, after which a heavier pressure may be used with less danger of the teeth crumbling at the top or breaking off at the base. Every file should keep a partially worn file to use first on the chilled or gritty skin of castings, or on a weld where borax or similar fluxes have been employed, or on the glazed surface of saws after gumming. In filing high tempered steel it will generally be found more profitable to use the finer grades of files, called 2d cut and particularly where anything like a fine finish is required.

MUSIC OF THE FLUTE.—That it is really the air which is the sounding body in a flute or other wind instrument, appears from the fact, that the materials, thickness, or other peculiarities of the pipe, are of no consequence. A pipe of paper, and one of lead, glass or wood, provided the dimensions be the same, will produce, under similar circumstances, exactly the same tone as to pitch. If the qualities of the tones produced by different pipes differ, this is to be attributed to the friction of the air within them, setting in feeble vibration their own proper materials. — *Sir John Herschel*.

RAILROAD CURVES.—When a train of cars is rounding a curve the greater weight is on the outside rail. The centrifugal force of the train round a curve tends to overturn the cars upon the outer rail, as the center of gravity of the mass is some distance above the top of the rail.

VENTILATION BY THE CHIMNEY.—A parlor-fire will consume in 12 hours 400 pounds of coal, the combustion rendering 42,000 gallons of air unfit to support life. Not only is that large amount of deleterious product carried away and rendered innocuous by the chimney, but five times that quantity of air is carried up by the draft, and ventilation thus effectually maintained. The ascent of smoke up a chimney depends on the comparative lightness of the column of air within to that of an equal column without; the longer the chimney, the stronger will be the draft, if the fire be sufficiently great to heat the air; but if the chimney be so long that the air is cooled as it approaches the top, the draft is diminished. — *Faraday*.

MAGNESIUM STEEL.—Magnesium also causes a remarkable change of structure in other metals. A coarse-grained steel becomes fine-grained on the addition of one-fifth per cent. of magnesium. In performing the experiments referred to, the magnesium must be introduced through a hole in the cover of the crucible after the oxygen has been first removed by the addition of a few pieces of charcoal. Without this precaution violent explosions are apt to occur. — *Ber. d. Chem. Gesell.*

TO HARDEN THE SKIN.—The constant use of the fingers in practicing the violin, piano and guitar, or kindred instruments, frequently become very tender and sore. The skin may be hardened by applying a strong solution of alum in water, or the tincture of white oak bark. A still better lotion would be a solution of tannic acid. Any drug store can furnish the acid, which should be dissolved in water.

INSOLUBLE CEMENT FOR BOTTLES.—Soften glue in cold water and melt it in the water bath to form a very thick paste. To this add good glycerine in quantity equal to the dry glue taken, and continue the heating to expel as much of the water as possible. This may be cast on a marble slab to cool, and melted for use as required. This is not soluble in alcoholic liquids.

LIGHTNING ARRESTER FOR TELEPHONES.—Surround the wire for a distance of three or four inches with a copper tube having a number of internally projecting points, which come very near the wire but do not touch it so as to interfere with its vibrations. The copper tube should be connected with a ground wire having good ground connections.

GOOD HEALTH.

Labor as a Form of Athletic Exercise.

Open-air labor is the most effective cosmetic, an almost infallible panacea against all kinds of bodily deformity. But the remedial virtue of labor, i. e., sound bodily exercise, is greater than that of open-air life *per se*; for among the rustic population of Scandinavia, Scotland, and Northern Germany, who perform a large portion of their hard work in-doors, we frequently find models of health and vigor; far more frequently than among the inhabitants of Italy, Spain, etc., who pass the greater part of their indolent lives in the open air.

But besides all this, athletic exercises have a moral value, which our social reformers have strangely failed to recognize; they afford a diversion and a vent to those animal energies which otherwise are sure to explode in debauch and all kinds of vicious excesses. The sympathetic thrill by which the mind accompanies a daring gymnastic feat, and the enthusiasm of athletic contests, form the most salutary, and perhaps the only normal gratification of that love of excitement which is either the legitimate manifestation of a healthy instinct, or else a wholly irremediable disease of our nature. The soul needs emotions as the body needs exercise, and the exciting sports of the palestra met both wants at once. We try to suppress these instincts, but their motives remain, and if thwarted in their normal manifestations they assert themselves in some abnormal way, chemically instead of mechanically, as Dr. Boerhaave would say, by convulsing the organs of digestion, since the organs of motion are kept in unbearable inactivity. In times of scarcity the panthers of China and Siam silence the clamors of their hungry children by dosing them with opium; and for analogous reasons millions of our fellow-citizens seek relief in alcohol; they want to hennup a feeling which they cannot satisfy in a healthier way.

After finishing his day's work the Grecian mechanic went to the gymnasium, the Roman to the amphitheater, and the modern European and American goes to the next "saloon," to satisfy by different methods the same instinct—a longing for a diversion from the dull sameness of business routine. There is no question which method was the best—the only question is which of the two had substitutes may be the worse: the brutalizing, i. e., soul-hardening spectacles of bloodshed of the Roman arena, or the soul-destroying poisons of the liquor shops? — *Dr. F. L. Oswald, in Popular Science Monthly*.

The Fur on the Tongue.

The nature of the fur on the tongue has been the subject of a study by Henry T. Butlin, F. R. C. S., and the results of his investigation are given in a paper read at a recent meeting of the Royal Society. The author finds that tongue fur consists chiefly of (1) debris of food and bubbles of mucus and saliva, (2) epithelium, (3) masses which at first appear to consist of granular matter, but which are the glea of certain forms of schistomycetous fungi. In order to ascertain the true nature of the glea, and to obtain it in a purer form, it was cultivated upon a warm stage. Several fungi were discovered, but only two of these were present in every instance, *Micrococcus* and *Bacillus subtilis*, and as the glea produced artificially was similar to that existing naturally in the tongue fur, it is believed the fur is composed essentially of these two fungi.

Micrococcus developed freely and abundantly, forming large masses of yellow or brownish yellow color. *Bacillus* did not develop, but existed in greater or less abundance in all the cases examined. It appeared to be identical with the *Leptothrix buccalis* described by Robin. Although it did not develop under artificial conditions, it is probable that development takes place freely upon the surface of the tongue. Its habitual occurrence there, and the presence of spore-bearing filaments, favor this view. Besides these fungi there were present in more or less abundance, *Bacterium termo*, *Sarcina ventriculi*, *Spirochaeta plicatilis*, and a larger form of *Spirillum* or *Vibrio*. The first of these fungi existed in some of the furs, and twice developed with great rapidity. The second was frequently present, and generally developed quickly, forming large masses of a yellow or yellowish brown color. The *Spirochaeta* occurred in only two or three of the specimens examined.

The slime between and around the teeth was found to consist of the same fungi as the tongue fur, but the rods of *Bacillus* were longer, probably owing to fewer disturbances.

THE SIGNIFICANCE OF SALT IN WELL-WATER. In Prof. Lattimore's report on the analysis of well-water, which was proved to be the cause of a serious epidemic of typhoid fever in Rochester, he lays special stress on the significance of the presence of common salt in well-water in general. No single indication, he holds, is of so great sanitary importance in judging of the purity or impurity, and consequently of the safety or danger, of any water. He proceeds then to show that, though from the universal diffusion of this substance in the air and in the soil, we should expect to find it in all waters, whether from rain, springs or wells, because of its extreme solubility, nevertheless, he argues, the quantity of salt that should be found normally from the cause named in well-water is extremely small, and therefore, whenever "it rises above a very few grains per gallon, it becomes certain that it comes from some other source than the soil;" and he concludes with the logical inference that, as nearly all the salt used for domestic purposes escapes by the way of two channels, the water-closet and the house-drain, we should therefore expect, "what is always found on examination to be true, that, whatever sewage may or may not contain, it always contains salt." A fuller abstract of this portion of Prof. Lattimore's report will be found in the *Popular Science Monthly* for July.

MUCOUS MEMBRANES.—Dr. Rolliu R. Grigg says there is no one medicine that can cure all cases of irritated and abraded mucous membranes and stop the waste of albumen. A variety of remedies is required to do this, in the different cases, and the treatment must be governed to a great extent by the peculiarities of constitution, and by the condition and the symptoms of each patient at the time the case is taken in hand. Furthermore, this is a diseased condition, where every case should be under the care of an educated, judicious physician, as much as severe cases of typhoid fever, diphtheria, or any of the other most intricate diseases. I will say, however, for the encouragement of all, on this now almost hopeless subject, that there is a series of most reliable physiological facts bearing directly upon the curability of all cases in the first stages, and which shows that of all tissues the mucous membranes are the most quickly and easily healed of any by proper treatment.

DIETETIC MEDICINE.—A subscriber sends us the following, which he says has restored many to health who had despaired of medical treatment, in cases of debility and blood-poisoning. Put the white part of a raw, freshly laid egg into a tumbler, add a wine-glass of pure, soft, cold water, which has been boiled. Drink this ten minutes before each meal. Perhaps, also, food containing albumen largely could be added to this. Distilled water or boiled water only—the principle involved being the destruction of germs which exist in the natural water, and may be thence transferred into the system.

ORGANIC RESISTANCE TO A BOILING TEMPERATURE.—Ch. Chamberland has found a microscopic organism which lives in nearly all liquid solutions of organic matter, provided that they have been previously neutralized by a solution of potash. It produces germs or spores which, when placed in neutral media, resist a boiling temperature for several hours. A temperature of about 115° (239° Fahr.) kills them very rapidly. — *Comptes Rendus*.

The Week.

Since our last issue the stock business has passed safely through a great variety of hazardous situations. Beginning with the sudden influx of stock held in the East, the indications pointed strongly to a panic. The action taken by Eastern journals in uttering the sayings of some innocent hear that seeks only his own advantage in being interviewed by an equally innocent interviewer, fully illustrates the tender condition of the public conscience in regard to stock speculations, and the ease with which a scare is created, causing the unloading of great quantities of particular stock—but "that's the way we make our money" in the stock business.

That the market rallied is due to the innate common sense of stock investors generally, who being on the ground here in person or through trustworthy agents, understand the real condition of our mines, and the object of the accidental interviews with scientific sharps. There is not and never can be a feeling of perfect confidence in this stock business, and hence it is not surprising that the condition may be said to have been "nervous" during the week.

The trouble lies with the bears. Old bears, young bears and even cubs are hard at work. As fast as one family of bears is chained up a new variety appears, and then the "wreckers" are again on the tapis manipulating with the stock of others or loaned for the occasion. There must be both hulling and hearing, but their need not be operations on borrowed stocks. Shorting stocks in this manner is a two-edged sword, and those who loan their stocks for this purpose will have cause to regret. Let stocks be sought for a rise, that is business, and legitimate, but demoralization is caused by loaning stock to illegitimately influence the market.

Failing to Deal with all the Factors.

There is a class of economists who, when studying the question of the profitability of gold and silver mining on this coast, have a habit of considering only the amount of assessments levied, and the dividends disbursed on account of this industry, and, pointing to the excess of the latter, claim a balance in its favor. This showing is well enough so far as it goes, but it scarcely exhibits the true state of the case. These figures fail to reach bottom facts. In their way of treating the subject these statisticians overlook a great deal that ought to be considered. They fail to deal with all the factors in the case. They leave out items of expenditure and elements of loss that should appear in the reckoning, for if a business is to be credited with its successes and its profits, it should be debited with all attendant outlays and failures. The imperfections of such methods of measuring the value of this industry is made apparent by the very compilations upon which these writers depend for their facts.

For example, the California mine on the Comstock is credited in these assessments and dividend tables with more than \$30,000,000 net earnings, with not a cent for assessments charged against it. In the case of the Consolidated Virginia, over \$40,000,000 in dividends are off-set by less than half a million contributed in assessments, and yet several millions must have been expended in the purchase, development and equipment of these properties.

But these are insignificant items compared with the labor and money that have been expended upon other mines lying along and adjacent to the Comstock lode, none of which have ever figured on the list of assessments collected or imposed. And these Comstock outlays of which no record has been kept, shrink in turn to almost nothing beside the enormous disbursements equally profitless and alike unrecorded made elsewhere on mining account. These things, belonging happily now to the past, are not hers recalled with a view to disparaging this branch of mining. But being a pursuit that can afford to stand on its merits it is only fair that these off-sets should be charged up against it.

A slight inspection of this class of statistics under consideration will serve to disclose how little light they are capable of shedding on this business of mining for the precious metals, viewed in all its aspects and hearings. They are useful so far as they go—lucid enough but so little enlightening that not much more of exact and appreciative knowledge does this inquirer possess after than before consulting them. These tables tell us that Comstock shareholders for \$55,000,000 paid in assessments have received in return \$117,000,000 in dividends—net earnings \$62,000,000 in excess of outlays. The California mines, Bodie being left out, have, we are assured, absorbed a million and a half in the shape of assessments and returned just twice as much in dividends. Bodie mine owners have paid out one million and got back two. Other shareholders in properties scattered all over the mining regions have spent \$10,000,000 in assessments and received \$13,000,000 in dividends; all of which on the face of it and at first sight looks well enough, seeing shareholders, besides these large gains, still own the mines.

But these figures fail to represent the vast amounts of money and labor expended on properties of little or no value, nor do they inform us how much more these dividend-earning shares cost the holders than was ever reimbursed to them. By these figures the California mine is made to appear self-sustaining from the first—as a property that never required the aid of assessments, whereas purchasers of that stock really paid enormous assessments in the shape of high prices for their shares. In these tables the mines of this State, which have produced a billion in gold, are hurlished through the statement that they have been assessed one million and a half and divided five millions.

Verily these are explanations that themselves need explaining, not that it is important we should be able to cypher out the sum total of these assessments and dividends to a fraction. Our people have seen fit to assess themselves to the extent of many millions in the furtherance of this industry, and that without saying much about it. And there have been other dividends than those that figure in connection with stock operations. They consist of the earnings that have been distributed among the working classes and small capitalists throughout a period of thirty years, nurturing mining, aiding other callings and sustaining the very framework of society.

But these statisticians love to hussy their heads with figures, and theorists have a penchant for the ideal, and something may be pardoned to these infirmities. Practical mining is, however, a thoroughly realistic sort of pursuit. It is a bundle of actualities. In dealing with it we know where we are and what we are about. Language has here a determinate meaning and figures a fixed value. But when we enter the speculative realms of the business, all is changed. Things are not what they seem. Facts become fictions and figures lie; and so we miscalculate and all are misled.

We should aim to be honest if we cannot always be exact in figuring on mining. It is a business that calls for no concealments and requires that no false lights be held out to allurs

investments. Backed by its two billion production it needs no apologies. It has made its mistakes and brought losses to many. But it is worth all it has cost, and it is doubtful if any other industry of equal importance has been matured in shorter time or with fewer sacrifices. It took a hundred years to place cotton planting on as good a footing as mining occupies to-day, though a much more simple business in itself. Mining for these precious metals is a complicated and difficult pursuit, and we have need for all the reliable information easily obtainable upon it. But these tabular statements, though often a convenience, enlighten us but little on its inner history—throw but a faint light on its lower levels.

The Mechanics' Fair.

Exhibitions are commercial safety valves. The heavy load of secrecy occasioned by the desire of business men to overreach each other and obtain reciprocal remunerative advantages, finds ease and comfort in fairs and industrial displays. The progress made in the privacy of workshops are here made known to the public. If these means were not taken to show and be shown, business would become stagnant, and valuable exhibits remain in obscurity, a loss to their originators. This creation of a new demand is effected by the display of an object, suitable to that new demand. A mere advertisement, although possessing a certain amount of publicity, acquires an immense power when coupled with the methodical arrangement of a public exhibition, in bringing before the public notice the particular points of novelty and utility, as regards mechanical contrivances and economical features in relation to agricultural productions. Like wine and tobacco, exhibitions have numerous opponents, but are in large and ever-increasing demand. They have made the tour of the world, and are now at the Antipodes. They have an incentive in the deep interest manufacturers and merchants feel, in bringing their industrial products before the people. Local interests unite with national interests, and combined, form a power which excites the inventive genius of outsiders and foreign competition.

What is true in general is true in particular, as well in logic as in human affairs, and he who would deride a public exhibition of the kind now proposed should first intimate a more available plan for promoting intercommercial competition. All of the industries in this city may be visited and examined. Goods may be priced and objects to suit the most fastidious taste may be selected. But the probability is that in such a vast emporium, scattered over so many miles of streets and highways, many things more suitable, and of more utility to the average demand, would be overlooked. Hence the requirement of concentration in some certain public locality, where the eye can, at a glance, take in the various objects presented to its view.

The system of local and national exhibitions has become thoroughly established, in fact the local is a stepping-stone to the national or universal, and to deride or neglect these now necessary adjuncts to commercial activity is equivalent to attempting business without capital, store room or advertisement. It is always unpleasant to speak in a complaining key, but it appears to us that a more general interest could be infused into our own local Mechanics' fair. A few days and the fair will open. Will it be a success? The producer alone can, by his actions or omissions, answer the query, Yes, or No. Yes, to his credit morally and pecuniarily. No, to his detriment politically and financially.

PACIFIC COAST PRODUCTS AT THE MECHANICS' FAIR.—Mr. W. H. Murray, Business Manager of the San Francisco Journal of Commerce, has been requested by the managers of the Mechanics' Institute fair to secure a display of California products for exhibition. The displays made by this gentleman with the aid of producers in former years, have attracted much attention, and given visitors a much better idea of the quality and variety of California products than they could otherwise have obtained. This year it is hoped a much better and larger display will be obtained, and all producers are requested to contribute material which they regard worthy of exhibition. A circular has been issued which announces that the display will consist of cereals, wine, wool, minerals, ores, tobacco, silk, flour, woods, and other objects, natural or cultivated, of curiosity or importance. A special feature of this exhibit will be a magnificent display of tropical and semi-tropical fruits and fruit-bearing trees, raised in California. All who are able to furnish anything worthy of display in any of the above lines are requested to ship per Wells, Fargo & Co., who will deliver them to the Mechanics' fair building, Mission and Eighth streets, S. F. All matter should be way billed "S. C." Credit will be given to each party contributing to the exhibition, and all are requested to be particular in giving name of grower, and place where grown.

A STEAM tramway from Rome to Tivoli was recently opened with a large popular demonstration. Tivoli, it will be remembered, is where the finest Pinafore ship ever put upon any stage, etc., is to be seen.

The Several Dunderbergs.

In answer to a letter from the East making inquiries about the Dunderberg mine we may say as there are several mines, bearing this name we are at a loss to know which particular one is by the writer inquired of. There is to our knowledge a Dunderberg mine in Colorado, Nevada and California, and we believe also one in Utah. The Colorado mine is a valuable property and adjoins the largely productive and profitable claim known as the Terrille. For several years operations upon it were much retarded, and at times wholly stopped through legal complications, all of which are now happily disposed of. The mine yields much good ore, making a bullion production of about \$25,000 per month, with a fair margin for profit. Without any doubt the Colorado Dunderberg is a mine of merit, having a prosperous future before it.

The Nevada Dunderberg is located at Eureka in the midst of a group of notable claims, being in close proximity to the Eureka, Richmond and the Ruby mines. This latter is owned by an English company who, having also purchased the Dunderberg, the two have been consolidated and are now being worked as one mine. Both claims make a good showing of ore, the Ruby having been extensively developed.

The California Dunderberg lies in Mono county, a short distance west of the Bodie mines now making such a splendid exhibit of mineral wealth. It occupies a section of an immense ore-bearing lode that here strikes north and south along the easterly base of the Sierra Nevada. It has been opened by means of a tunnel, that fails, however, to drain its lower levels, which in the absence of pumping machinery have filled with water. As a consequence, nothing has for some time past been done here in the way of ore extraction. A first-class mill has been put up at this mine, a large amount of money having been expended upon the property, which with a comparatively small outlay could be brought into a condition fitting it for large and profitable bullion production, extensive ore reserves being already opened up in the mine. The natural facilities that exist here for the prosecution of mining are nowhere excelled, the whole country being covered with magnificent forests and water being present in unlimited supply. The property, though for several years neglected by reason of this financial embarrassments of the owner, is admitted on all grounds to be one of great value, and now that attention is being strongly turned to that district it will no doubt soon be started into life again.

Labor and Wages.

There is more truth than poetry in the wail of the *Mining World and Engineering Record* about the lack of consideration of working men for the interests of their employers, and says that the competition of foreign countries with England is becoming more and more keen, and that the English as a people must exhibit greater qualities of skill, industry, and perseverance than of late, if England is to retain the supremacy which it has hitherto enjoyed. "Not merely are we being beaten out of the field, but foreigners are entering into competition with us on our own ground. French and German clerks are crowding into our warehouses, and even the field of manual labor is being filled by foreigners."

The Cunard company had the entire paneling of the steamship *Galtea*, executed by Japanese carpenters, the parquetry of the cabin floor on the main deck, and the iron work of this office of the company supplied from Belgium. It is admitted that these foreigners seem to take an interest in the work given them, while English workmen are utterly regardless of anything but short time and high wages. It is claimed that the English working classes by sacrificing the interests of their employers in strikes for shorter hours and higher wages, are bringing about the destruction of England's pre-eminence in the commercial world and by compelling capitalists to look out for laborers who will be devoted to their interests, are destroying their own prospects.

The strife of the laboring classes against capital, and the attempts to compel masters to pay more than the necessities of trade will permit, will bring only ruin to those who indulge in it, by diverting trade into other and foreign channels. This lamented condition of things in England should not be laid at the door of the working men. There are certainly grievances, perhaps on both sides, and it is a singular short-sightedness which cannot distinguish between the cause and the effect.

The rate of wages in England is very low, and the working hours longer than in this country, yet we are able to compete with British productions, so that the trouble cannot be attributed to the English laboring classes. National decay fostered by fossilized ideas incompatible with modern ideas, has more to do with the ruinous condition of things than the ingratitude of the British yeomen.

A FRENCH engineer now offers to build a ship railway across the Isthmus of Darien for \$5,000,000, one-tenth of the sum Capt. Eads agrees to do it for.

Mineral Veins.—No. 2.

In continuation of the article in our last issue on the above subject we learn from Prof. Le Conte's "Geology" (Appleton & Co., N. Y.), some of the important laws affecting the occurrence and the richness of metalliferous veins, and propose in another article to give a theory of metalliferous veins, which appears to us to be incapable of refutation as an entirety.

Metalliferous veins occur mostly in disturbed and highly-metamorphic regions, where the strata are tilted, and folded, and metamorphosed. The tilting and folding are necessary to the formation of fissures; and the conditions under which metamorphism takes place seem necessary for the subsequent filling with mineral matter. Mineral veins, therefore, occur mostly in mountain regions and in the vicinity of more or less obvious evidences of igneous agency. Lead veins seem to be an exception to this rule. They are often found in undisturbed regions, where the rocks are entirely unchanged. The rich lead mines of Illinois, Iowa and Missouri, are notable examples, the country rock being horizontal, fossiliferous limestones of the Paleozoic era.

Metalliferous veins occur mostly in the older rocks. In Great Britain, for example, no profitable veins occur above the trias. This rule, which was regarded as of great importance by the older geologists, is not so regarded now. There seems to be no close connection between the occurrence of metalliferous veins and simple age alone; the connection is rather with metamorphism. Metamorphism is most common in the older rocks, and becomes more and more exceptional as we pass upward. The occurrence of metalliferous veins follows the same law. But when the newer rocks are metamorphic, they are as likely to contain veins as are rocks of the older series. The metalliferous veins of California occur in jurassic, cretaceous and even tertiary strata; but these strata are there highly metamorphic and strongly folded. In Bohemia, also, and elsewhere, metalliferous veins occur in the higher series (Phillips, p. 549).

Parallel veins are apt to have similar metallic contents, while veins running in different directions (unless at right angles) are apt to contain different metallic contents. Thus, the nearly east and west lodes of Cornwall, *a, a, a* (Fig. 1), contain tin and copper, while the north and south courses, *b b*, contain lead and iron. The auriferous veins of California are parallel to each other and to the Sierras, except a few smaller ones, which are at right angles to these. The reason of this rule is, that parallel fissures belong to the same system, and were therefore formed at the same time, broke through the same strata, and were filled under similar conditions, and therefore with the same materials; while fissures running in different directions were probably formed at different times, broke through different strata, and were filled under different conditions. Thus, the east and west veins of Cornwall break only through the trias, while the north and south veins break through the cretaceous. The auriferous veins of California all break through the jurassic; they, or their fissures, were all produced at the same time, viz., at the time of pushing up of the Sierras.

A change of country rock of an outcropping vein is apt to determine some change, either in the contents or in the richness of the vein. Nevertheless, there is not that close connection between the nature of the country rock and the vein contents which obtains in infiltrative veins. The reason is, that infiltrative veins derive their contents entirely from the wall-rock on either side, while fissure veins derive their contents from all the strata through which they break, even to great depths, and especially from the deeper strata. The nature of the surface or country rock is, therefore, only one factor, determining the vein contents.

Metalliferous veins are usually richer near their point of intersection with granite or with an igneous dike, especially if the strata have suffered metamorphism. This shows the influence of such heat as is present in metamorphism, in determining the metallic contents.

If two veins cross each other, especially if at small angle, one or both are apt to be richer at the point of crossing. No sufficient reason has been given for this law. It is probably due to the reaction of waters bearing different materials circulating in the two fissures.

Since veins are the fillings of fissures, they are often slipped by each other or by dikes or by simple unfilled fissures. If a metalliferous vein is thus slipped, the footwall of the vein has usually gone upward and the hanging wall dropped downward. The great importance of this law in practical mining is sufficiently obvious.

The surface indications are to be learned by attentive observation in each case.

Our knowledge of the conditions under which, and the chemical process by which, fissures have been filled with mineral matter, is yet, unfortunately, very imperfect. Many vague and crude theories have been proposed. Some have supposed that they have been filled in the manner of dikes and granite veins by igneous injection; others, that these fissures, opening below into the regions of incandescent heat, have been killed by sublimation, *i. e.*, by vaporization of certain materials and their condensation in the fissures above. Some suppose that electric cur-

rents, such as are known by observation to traverse certain veins, have been the chief agents in the transference and accumulation of the mineral matter. Still others have thought that great fissures have filled in the same manner as the smaller fissures and cavities of every kind found in the rocks, viz., by infiltration of soluble matters from the fissured rocks. There is certainly considerable analogy between small infiltrative veins and great fissure veins in their mode of formation; yet there is a decided difference. The fillings of infiltrative veins are derived, in each part, entirely from the bounding rock on either side. The fissure is filled by a lateral secretion from its walls; the broken rocks heal themselves "by first intention" by means of a plasma oozing from the sides. But great fissure veins derive their contents in each part from all the strata to great depths, and especially from the deeper strata. Hence the contents of these veins are far more varied.

Exhibition Advantages.

A private display of goods, wares and merchandises, in the windows of a merchant on some busy thoroughfare, is intended to attract the attention of transient purchasers and to excite a desire to buy in those who would not think of purchasing if some attractive article was not exposed to view. So essential is this display that the merchant who retains his stock in a dim, disagreeable, or unexposed locality, is quite sure not to retain many old customers or acquire any new ones. The general independence manifested by our people is very clearly observable in their seeking for goods in localities most suitable to them. The general idea of "good will" as applicable to business does not obtain to any great extent in this country, and we find purchasers buying at one place to-day and at another to-morrow, wherever greater advantages are offered.

Now an exhibition is nothing but a mart, a concentration of the best articles manufactured,

Fair Results.

The grand result of the Centennial exhibition at Philadelphia, in 1876, was the unparalleled orders that came from foreign countries to the United States for American production. Orders for locomotives and engines generally, have in certain localities, become so numerous that the home supply has been crowded out in providing for outside demand. Other productions are spreading over the whole world, even to the detriment of other countries, who in spite of cheap labor cannot compete with us.

South Africa sets up a wail over the fact that that portion of the world is supplied from America with lamps, hand-trucks and a thousand other articles of improved construction, and far better value than got from England.

Then, again, 15 cargoes of all kinds of miscellaneous articles, from a wagon to a shoe-peg, were sent from Boston to Australia, in 1878.

The British looms are being pressed so closely by American manufacturers that many English machine and cloth manufacturers are preparing to transfer their works to German soil!

Sprightly little Belgium, a giant by the way in inventive adaptations, proposes to establish for self-preservation a permanent museum in Shanghai, in which will be exhibited specimens of all descriptions of Belgian manufacture and produce. While the United States have already begun to move in Brazil, by establishing what is called the American "Bazaar" in Rio Janeiro, a permanent exhibition of American manufactures, a private enterprise.

Even Switzerland is distressed about her watch manufactories, being unable to compete with the United States in the world's market, or even in her own.

Even so wise a statesman as Gladstone declares that the scepter of commercial supremacy is passing away from England to the United States.

The continual struggle against American articles, the warnings of the foreign press, and

MAP OF CORNWALL LODES.

grown, or for sale in a whole city, county, state, country, or of the world, as in universal exhibitions. Here the intending purchaser can find the requirement of every demand displayed before him in a small space, and can examine goods, and witness the workings of machinery, or ascertain what his neighbors are doing, with ease and comfort to his physical nature, and with instruction and profit to his moral characteristics. The financial depression that afflicts so many at present requires an examination of prices, and those seeking to invest naturally desire the greatest quantity of first-class goods for the least money.

This can only be done with satisfaction at a general rendezvous of trade, such as our Mechanics' fair, and those who do not exhibit, or who do not sufficiently extol the merits of their wares to the public through the medium of advertisements must not be surprised at a vast diminution of their sales, and corresponding loss of profits, although their goods may be as good as those better advertised.

The sharp competition that exists will not permit a "take it or leave it" spirit on the part of the salesman. The public must be offered inducements to purchase. At the Fair will be assembled thousands from every part of the State, thousands who have been waiting for this very Fair to see what is in the market before purchasing, and it behooves every exhibitor to exert himself in the direction of securing the coin laid away for purchases at the Fair. A certain sum must be laid aside for the purpose of advertising, for in these times it is useless to expect to make money without such an investment. Money must be earned, and the profits are correspondingly large in proportion as the articles are better known.

All branches of business are dependent upon each other for support, and to patronize one business is to influence others. There is always something more desired by purchasers than our next neighbor may have if we have not, and so on all along the line. Demand cannot be created so largely in ordinary business, but at a general mart or exhibition a demand is created which is felt for a long period. Then, too, witnessing the latest devices side by side, inventive genius is excited to supply deficiencies which always exist in human affairs.

MINISTER WELCH having resigned the English mission, immigration to Washington is immense.

Evans' Amalgamator and Concentrator.

George R. Evans of this city has recently obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for an improved apparatus for amalgamating and concentrating the precious metals, saving sulphurets, etc. The apparatus consists in the novel combination of a pan having a horizontal reversing movement, with a series of arms or blades having a similar motion in opposition to that of the pan, said blades moving within the pan. These blades have each an adjustable removable sheath formed of copper, or other suitable amalgamated or plated metal, and they are connected with a slide moving in a guide and having an operating lever, by which they may at pleasure be lifted out of the pan.

The pan is charged with the proper amount of pulp, tailings, or with auriferous earth, if used in placer mining, and a sufficient quantity of water is introduced. It is then set in motion, when the reverse movements of the pan and blades thoroughly separate the heavy valuable portions from the lighter earth or pulp, and allow them to settle to the bottom.

The silver-plated or amalgamated sheaths of the blades will be brought into contact with all particles of float-gold or amalgam which are too light to settle by specific gravity, and they will thus be taken up and saved. The blades may at any time be raised and the sheaths taken off, cleaned and replaced, after which the pan may be again charged.

The form of the lower part of the pan is as nearly as possible that of the common miners pan in ordinary use in hand work for washing placer gold, and the peculiar movement given it, and the contrary movement of the blades, produce an effect upon the heavier and more valuable particles which causes them to work to the bottom.

Every miner knows the peculiar shake and rocking motion it is necessary to give to a miner's pan in washing out gold, and knows also that there is a knack in doing it by hand only learned by experience. Mr. Evans, who is an old miner, has endeavored to imitate this peculiar motion, by suitable mechanism, so there shall be no variation in the movement, but the process will be the same at all times. The contents of the pan are moved by the blades or arms in a contrary direction to the movement of the pan, which is precisely the action which takes place in a pan which is worked by hand in placer mining.

The device is capable of working a low grade of pay dirt or sand at a profit, and in working silver ores it takes the pulp directly from the pans or batteries and enables the inventor to dispense with the settlers. He is also enabled to dispense with blanket sluices. The fine floured quicksilver and sulphurets, which are usually lost in settlers, are saved to a greater extent in this separator, as there is no overflow, and the counter action of the blades and pans tends to cause the light particles to sink to the bottom of the pan by reason of their specific gravity.

Small-sized portable machines made in this form are suitable for placer mining, and may be worked by hand like a rocker. The large-sized machines for working pulp or tailings are worked by power. A series of the pans may be worked together when a large quantity of dirt is to be washed. The pan is made with partially converging sides, so that when the blades act upon the contained mass of pulp they will tend to concentrate the more valuable portion to the bottom. The crank arm is fitted to a feather on the shaft so that the shaft may be raised at any time while the blades are in motion. The pan is provided with openings whereby to draw off the contents from any level as desired.

The present settler loses a great deal of floured quicksilver, because there is no reverse movement, and the constant agitation keep it in suspension, and allows it to pass off. In this machine the amalgamated blades catch this floured material, and in case a quantity collects and is dislodged from the blades, it has acquired sufficient specific gravity, by aggregation of particles, to settle to the bottom, where it is caught. The main loss of quicksilver at present is in the settlers, which this machine is intended to replace, so that all the fine material may be saved.

The machine may be used to pan down earth from placer mines, or concentrated material from sluices, much quicker and more readily than by hand. There are many places on the rivers and creeks where it will not pay to work with rockers on a small scale. A machine of this kind, which will handle a comparatively large quantity of earth in a short time and with a small quantity of water, and not much expenditure of power, would be very useful in such localities.

In gold mills this machine takes the material direct from the battery, and is intended to save gold, quicksilver and sulphurets from the batteries, without the intervention of copper plates or pans.

The owners of this patent are George R. Evans, Garret H. Hopper and Joseph Hutchinson. A working model of the machine may be seen at Hawkins' machine shop, No. 210 Beale street, between Howard and Folsom, where it may be examined by those interested in such devices.

SEND in exhibits for the Mechanics' fair to open on Tuesday, Aug. 5th, and be prepared for a revival of trade.

C. C. Bither's Apparatus for Obtaining Metallic Copper from its Solutions.

Patented March 18th, 1879. Will precipitate with steam in three hours, requiring no machinery to run it. Cost of constructing apparatus, \$75. The old cylinder process takes four hours to precipitate and costs from \$1,200 to \$1,500 to construct, besides the machinery to run it. For right to use my Precipitator address C. C. BITNER, Spenceville, Nevada County, California.

State, County and Individual Rights for Sale.

THE ELKINS "BOSS" GOLD AMALGAMATOR.

Is the Best, Simplest and Cheapest
 Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—the heaviest piece weighs 160 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 1-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 381 Pine Street, - - SAN FRANCISCO.

Improved Grounds For Sale NEAR SAN JOSE.

The subscriber offers for sale a tract of land, 40 acres in extent, located half a mile south of the road from San Jose to Alum Rock, and four miles from San Jose—directly in the warm belt of the foothills. The grounds are pleasantly and conveniently located, and under a high state of cultivation.

Five Acres in Orchard,

—CONSISTING OF—

Orange, Lemon and Lime Trees, Nuts,
 FIGS, BANANAS,

Together with a great variety of other Fruits, large and small, and GRAPES. The Bananas ripens readily in this locality. TWO ACRES are set off for an

ORNAMENTAL GARDEN,

Which is now filled with Shrubs, Flowers, and a fine growth of ORNAMENTAL TREES, 170 in number, now 10 years old. In connection with these grounds there is now a

Small Cottage and Farm House,

Well built and hard finished. On the higher ground there is a

FISH POND,

40 by 80 feet in extent, and 8 feet deep, well stocked with Carp and Trout. The pond is supplied with water from a never-failing spring a few feet distant, which delivers 24,000 gallons of water every 24 hours the year round. The pond is at an elevation of 20 feet above the house, and from it pipes are laid for irrigating the orchard and garden, and supplying the house.

The balance of the place is now devoted to grass and grain, but may be improved for orcharding or other cultivation if desired.

This place affords a rare opportunity for anyone desirous of securing a well-improved locality for a country residence, and will be sold at a great bargain. For further information apply either at this office or of the proprietor on the premises.

Barlow J. Smith, M. D.

Consulting Physician,

Professor of Phrenology and
 Mental Hygiene.

Proprietor of the Smithsonian Medical and Phrenological Institute, 635 California Street, above Kearny. This Institute, by combining medical hygiene with the various Water Cure treatments and the most powerful Electricized Horseshoe Magnet in the world, claims to cure speedily and permanently all forms of acute or chronic nervous derangements, Brain, Spinal and Heart diseases, St. Vitus Dance, Palsy, Epilepsy and all Rheumatic, Liver and Kidney troubles. The institution has for the past 20 years made a specialty of treating all forms of weaknesses and diseases peculiar to males and females. By the use of hygienic remedies and electro-motricity the worst forms of impotency and seminal weakness in males and sterility in females are speedily and permanently overcome. Hygienic board, with or without rooms. Terms moderate. Electro-thermical, Russo-Turkish and Medicated Baths given daily. Mrs. Dr. Smith as Matron has charge of the female bathing department.

DR. SMITH has practiced Phrenology the past 30 years, and during the last 20 years has been constantly using the science connected with Physiognomy, in examining or diagnosing disease in this city, and claims to have made discoveries in the SCIENCE OF PHRENOLOGY that enables him, by an examination of the head, even blindfolded, to determine the disease to which the person is constitutionally subject, or whether the disease at the time afflicting the person, is the result of accident or hereditary weakness, whether CONSUMPTIVE, DYSPETIC, RHEUMATIC, APOPLETIC, NEURALGIC, LEUCORRHEAL, or SEMINAL. Especially does the form of the head indicate the strength of the uterine, genital or reproductive system. The head is also an index of the natural strength of the lungs, heart, stomach, liver, kidneys, spleen, back or vertebra, and it determines the power of the system in warding off and overcoming disease of all kinds. Ladies or gentlemen, desirous of obtaining a thorough and correct Phrenological examination with Fowler and Wells' charts, will meet with a respectful reception at its consulting rooms. Parties can depend upon a reliable delineation of the character of their intimate male or female friends, by presenting a clearly defined photograph. Phrenological or Physiognomical examinations without charts, \$1.50; with charts, from \$2 to \$3.

INVITATION TO INVALIDS

And all persons who are in any way out of health, who desire to know the nature and causes of their disease, may avail themselves of an examination through phrenology in regard to health free of charge, between the hours of 9 A. M. and 8 P. M. Sundays from 9 A. M. to 12 M.

NATIONAL SAFETY PAPER

FOR CHECKS, DRAFTS, ETC.

A sure protection against the raising of Checks and Drafts. Merchants should have their Checks and Drafts printed on this paper for self-protection.

H. S. CROCKER & CO.

Agents for the Pacific Coast.

The Greatest Invention of the Age!

MACKINNON PEN.

THE NEW WRITING INSTRUMENT.

24 Geary St., San Francisco.

NOTICE

TO THE

MINING PUBLIC.

MESSRS. RANKIN, BRAYTON & CO., of the Pacific Iron Works, are the only parties authorized to manufacture HOWELL'S IMPROVED WHITE FURNACE under the License of this Company.

THE STETEFELDT FURNACE CO.,

By C. A. STETEFELDT, President.

Referring to the above, the undersigned would call attention to the fact that by a compromise recently effected with the STETEFELDT FURNACE COMPANY, they have secured the use of all the patents of said Company applying to

Revolving Cylinder Furnaces,

And are thus enabled to give purchasers the license of all patent claimants, to-wit:

WHITE, HOWELL, THOMPSON,

— AND THE —

Stetefeldt Furnace Company,

Thereby avoiding all further litigation in reference to these rival claims. The great

SUPERIORITY OF THE FURNACES

Embracing these patents has been satisfactorily demonstrated. There are now some thirty of them in operation in the various mining districts of the coast, operating in all cases with economy and satisfaction, working in many localities

THE BASEST AND MOST REFRACTORY ORES UP
 TO 90 AND 95 PER CENT.

By an improvement—the patent for which has recently been allowed—this Furnace can be readily adjusted so as to work with equal facility and effectiveness all classes of ores.

The following are some of the Mining Companies who have recently adopted this Furnace, the most of which are new in successful operation, many of them running two and some three and four Furnaces.

NEVADA—Grand Prize, Star, Martin White, High-bridge, Columbia, Alexander, Paradise Valley, Jefferson, Leopards, Eagle, Endowment, Independence.

ARIZONA—Tiptop, Tiger, Peck, Hackberry, Corbin, Tombstone, Bradshaw.

OREGON—Monumental.

MONTANA—Alice Mine, Butte City.

MEXICO—Trinidad, Harnidguera, Plomosa.

PERU—Cerro de Dasco.

RANKIN, BRAYTON & CO.,

Pacific Iron Works.

CAUTION.—All persons are hereby cautioned against buying from other parties Furnaces embracing the improvements covered by the patents above mentioned, as they will be vigorously prosecuted and involved in heavy damages.

WASHING! WASHING!

Prices Reduced! Prices Reduced!

La Grande Laundry,

13th Street, Between Folsom and Howard.

PRINCIPAL OFFICE,

648 Market Street, S. F.

Office open from 7 A. M. to 9 P. M. Saturdays to 11 P. M.

Washing called for and delivered to any part of the city free of charge.

All orders receive prompt attention. For circular and price List apply at the Office,

648 Market St., San Francisco.

PALACE RESTAURANT

218 Sansome St.

[Lunch ready at 10 A. M.] Resident business men and visitors from abroad will be wise in giving this place an early call. Examine of fare and prices.

HERMAN H. HORST, Prop'r.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET.
Near First and Market Streets.

Ores worked by any process.
Ores sampled.
ASSAYING in all its branches.
Analysis of Ores, Minerals, Waters, etc.
WORKING TESTS MADE.
Plans furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines; plans and reports furnished.

E. HUNN,
C. A. LUCKHARDT,
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS,
CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, Etc.

512 & 518 Washington St., San Francisco

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.
Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

CARROLTON

Writing Papers

Notes, Letters, Legals and Foolscaps, all weights.
The best CHEAP Paper in the World.

H. S. CROCKER & CO.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

SANDERSON BROS. & CO.'S

Best Refined Cast-Steel.

Warranted Most Superior for Drills, Hammers, Etc.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock and for sale

At No. 417 Market St., S. F., - H. D. Morris, Agent.

FOR SALE.

COMPLETE THRESHING OUTFITS,

Consisting of HOADLEY'S STRAW-BURNING ENGINE, 15 horse power, JACKSON'S REMODELED PITT THRESHER, with Feeder, Elevator, Derrick, Forks and Water Wagon,

\$2,500 to \$3,000,

Fully Guaranteed to Equal the Best Improved Outfits in the Market.

Also, one four-sided, six-inch SMITH'S MOLDING MACHINE, and one HOADLEY WOOD-BURNER 12 horse power, at a bargain. Also, new 34-inch Thimble-Skein Wagons at \$75, and 10-foot WINDMILLS at \$80.

Machine Work and Castings of all Kinds to Order.

— FOR CIRCULARS ADDRESS —

Jackson Agricultural Works,

S. E. Corner of Sixth and Bluxome Streets, near S. P. R. Depot, San Francisco.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London. Etc., Etc.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

PROPRIETOR.

Machinery.

GOLD AND SILVER
Grinding and Amalgamating
MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S
Wrought-Iron Frame
FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular. We are furnishing all the Machinery for a 10-Stamp Old Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs,) S. F.

[CONTINUED FROM PAGE 69.]

plenty mors of the same sort. The Little Oak lode, in Dead Mule gulch, the property of Montgomery, Odor Bros. and the *Prospector*, is growing extremely rich. Two shafts are being sunk on the claim, one of which at seven ft. has shown up a well-defined vein three ft. in width, the ore from which, at the depth of eight ft., yesterday assayed 600 ounces.

ITEMS.—Register, July 13: It is said that on the Gunnison and San Juan a gold lode was discovered a few days ago, carrying free gold from rock down three ft. The rock assayed \$3,400. The Golden Fleec, located at Pica-yunc gulch, two miles from Animas forks, produced surface gold assaying as follows: Gold, \$3,051 ounces; coin value, \$161,430; silver, 5,593 ounces; coin value, \$6,293.76; total, \$167,233.76. From 300 pounds of second-class ore was obtained, by mill run, 10 ounces gold, 53 ounces silver. From 1,331 pounds of third-class ore was obtained 5 ounces gold, 41 ounces silver. The Golden King, an extension of the Golden Fleec, produces ore from pay streak 12 inches wide, assaying 3 ounces gold, 417 ounces silver, a total valuation of \$354.37. At Mineral Point the mines are active, with good ore on most of the dumps. In the San Miguel district the Lena, at present working, shows a pay streak of high-grade copper, assaying 800 ounces in silver per ton, with a trace of gold. In this diamond tunnel the vein is over four ft wide, carrying good ore the entire width. From the Susquehanna 13 tons were sampled and promise a run of at least 250 pounds to the ton. From the Aspen mine 100 tons of ore have been taken that will average 175 ounces in silver to the ton. Rich float has been found in Hansen creek, near the Burro Cabin, indicating the existence of a valuable silver-bearing vein.

IDAHO.

ITEMS.—World, July 22: A piece of ore from the bottom of the Montana shaft assayed \$200,000 per ton. The soldiers have found some very rich ore at the mouth of Isaac creek on the Middle Fork of the Salmon. It is as rich as any at Yankee Fork. In the Banner district, parties have located a mine discovered by them one mile east of the Banner. They have named it the Silver Belle. Two men are at work sinking a shaft on it. From Deadwood we learn that two companies of white men, Morlan & Staley and Wise & Co., and two companies of Chinamen are engaged in placer mining there. They got to work early last spring and have had a good run. A good many men are in there prospecting for quartz. Wise & Co. will commence crushing ore from a mine owned by them in an arastra in a few days. The news from Yankee Fork is discouraging. There is some rich rock here, but far from being in such quantities as represented. The country rock is porphyry and is filled with iron pyrites and sulphur, containing no silver or gold, and looks, to one not familiar with that kind of ore, to be rich. Three arastras are at work here with the finest kind of water-power, and the ore worked will not assay \$75 a ton, when they claim they are \$2,500,000 in the mine. Many of the mines rich on top have run out at a short depth.

MONTANA.

ITEMS.—Miner, July 22: The Dexter mill was shut down a day or two ago to remain closed about a week during which time he made the changes necessary to convert the mill from a dry to a wet crusher. The smelters, in which the owner of the Dexter is interested, will soon be in operation, when ores too base for free-milling processes can be worked to better advantage by smelting than by roasting and amalgamating. Working as a wet crusher, the Dexter will reduce five tons per day more than its present average, at a labor outlay of two men less than the force employed in dry crushing. The introduction of the apparatus required in wet crushing will not involve any change in the apparatus heretofore in use. In future the mill can be used either as a dry or as a wet crusher as it manager may elect. The Cornish rolls, sampling mill, etc., of the new smelting works were put in operation last week, and will hereafter run as occasion may require. Ores are now correctly sampled, and purchased at their true market value by the smelting company. Considerable gold dust is being brought into town from Emigrant, Bear and Greys gulches. Several thousand dollars' worth has already been purchased this summer by Messrs. Story & Wilson and Bozeman merchants. Tom Garvey pounded out \$3 from one pound of rock from Wm. Shields' mine, at the head of Spring gulch, near Summit, and says there is an abundance of ore in the mine that will discount these figures. Parties are contemplating the erection of another smelter at Glendals for the purpose of reducing ores from the Elm Orlu and other mines in the Burnt Pine district.

NEW MEXICO.

CURELLOR.—Leadville Reville, July 13: This is a new carbonate district near Santa Fe. The veins are very large and numerous, but the ore is not high grade at the present development, yet are quite uniform, averaging about 60 ounces of silver per ton.

OREGON.

ITEMS.—Times, July 25: Desselles & Co.'s Scott's gulch claim and the hydraulic mine of Wimer & Co., near Wald, are both running day and night. Water is falling generally and most of the large hydraulic companies will soon be obliged to suspend operations for the season. It is reported that certain parties mining on Silver creek took out \$240 in a single afternoon. It proved to be a pocket in the bedrock. A clean-up was commenced at the Sterling mine last week, which will conclude this season's operations. Some excellent ground has been washed off and a large amount of gold dust will no doubt be realized. The mine of Galt creek has all been washed for the season, with the exception of Pfeil Bros., who will not complete their clean-up until several weeks later. The spring run has proved a fair one, in a financial point of view.

New Discovery.—Bedrock Democrat, July 25: Messrs. Irvine & Co. have discovered new placer diggings, consisting of a large body of gray gravel, some five miles from Sparks, on the road to Eagle valley. The company is down some six or seven ft. in the gravel, and they are working with a new process.

UTAH.

ITEMS.—Silver Reef Miner, July 23: Bingham miners are turning their backs on lead ore and rustling among gold claims, which are quite numerous and more profitable. Sixty-four pounds of bullion valued at \$9,000, from the Crimson Mammoth, Tintic, was received in Salt Lake the other day. Hoisting machinery has been shipped from New York for the Russell mine, American Fork. This property belongs to the Excelsior mining company, headquarters in New York.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Gold Hill, July 19th, \$15,882.47; Hilleide, July 24th, \$4,300; Indian Queen, July 21st, \$5,078.07; Bodie Con., July 21st, \$10,611.67; Northern Belle, July 21st, \$7,518.94; Gold Hill, (I. T.) July 26th, \$7,157.78; Alexander, July 24th, \$5,706.19; Northern Belle, July 23d, \$5,474.82; California, July 23d, \$48,075.16; Hilleide, July 27th, \$4,000; Martin White, July 23d, \$7,015.60; Ophir, July 26th, \$24,361.95; Belle Isle, July 23th, \$26,000; Independence, July 28th, \$7,300; Belle Isle, July 28th, \$26,000; Christy Con., July 26th, \$5,347; Ophir, July 26th, \$24,361.95; Northern Belle, July 26th, \$10,151.41; Hilleide, July 29th, \$4,000.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

FOR THE WEEK ENDING JULY 22D, 1879.

217,766.—COMBINED RAIL AND TELEGRAPH CONDUCTOR—P. Barjon, Black Diamond, Cal.
217,770.—SIGHT FOR FIRE-ARMS—Wm. H. Brodri, Oakland, Cal.
217,807.—ELECTRO-MAGNETIC MOTOR—J. C. Ludwig, S. F.
217,740.—REARER FOR DEEP WELLS—Charles A. Mentry, Newball Station, Cal.
217,752.—GUN WIPER—J. P. Simonds, S. F.
217,835.—NOSE CLAMP FOR EYE-GLASSES—N. Watry, S. F.
217,841.—SEWER-TRAP ATTACHMENT—Wm. Wilson, Oakland, Cal.
217,775.—WATER-LIFTER—A. Colle, Modesto, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

IMPROVED SIGHT FOR FIRE-ARMS.—Wm. H. Broden, Oakland, Cal. Dated July 22d. This invention relates to an improved gauge-sight for hunting purposes; and it consists in placing on the ends of the barrel a clamp provided with a block or sight on the outer side of each barrel, and by covering the bird with the one which is nearest him in flying, the shooter is looking at the object at the proper angle out of the line of the barrel, so that the shot will hit as it comes in line. It also consists in providing the clamp with two shoulders and leaving a space between them, so that by looking through this space in shooting at a bird flying away both barrels will cover the object. Between the barrels there is an inclined groove and a movable sight may be used on it for greater accuracy in certain kinds of shooting.

AUTOMATIC GATE FOR FLUSHING SEWERS.—S. S. Tilton, S. F. Dated July 8th, 1879. This invention relates to a device to be applied to sewers having but little grade, for the purpose of storing up the flow of water and sewage matter until a considerable quantity has been collected, when it is allowed to be suddenly discharged so as to produce a current which will flush the sewer and sweep out any accumulations which may be deposited on it. The construction of this gate is simple and the parts are accurate in their operation.

SEWER-TRAP ATTACHMENT.—William Wilson, Oakland, Cal. Dated July 22d. The object of this invention is to prevent siphonage from the S-trap of waste pipes and sewers, and it consists in attaching to the trap a chamber connected to the lower end of the trap and the main pipe, so that it will fill as the trap fills. When water in the trap siphons off, the supply in the chamber passes slowly into the trap, thus filling it, closing a valve in the pipe and preventing the entrance of sewer gas into the room in which the basin is placed.

NOSE CLAMP FOR EYE-GLASSES.—Nicholas Watry, S. F. Dated July 22d. The object of this invention is to produce a more comfortable means for holding eye-glasses in position than has heretofore been used, and it consists in making the clamp, which is fitted between the frames to hold them in position on the nose, of spiral springs, instead of a stiff band, so that while the eye-glasses are held firmly in place, they do not annoy the wearer by undue pressure upon the nasal organ.

WATER LIFTER.—Alexander Colle, Modesto, Cal. Dated July 22d. This invention consists in a peculiar construction and operation of a water lifter, whereby a column of mercury is utilized in producing a vacuum which will lift water from a well. Double sets of tubes are used, one balancing the other, and the discharge of the water is utilized in increasing the weight of the tube in which the mercury is lifting the column.

CAMERON STEAM PUMP.—Messrs. Prescott, Scott & Co., (Union Iron Works) have the agency for the well-known Cameron steam pump. It is adapted to every variety of mining purposes, and applicable to general use. The tests to which this pump has been subjected leave no doubt of its merits and working capacity. We are always gratified to note the introduction of competent machinery on this coast. The severe strain required will admit of none but the best machinery, and we know the Union Iron Works have not failed to maintain our reputation in that respect.

In trying to please Tucson, Arizona, an old picture of that city has been published, which has been excepted to as not fairly representing the appearance of the city. We did the best we could—the trouble lies in the improvements keeping so far ahead of the photographer.

California Academy of Sciences.

The regular semi-monthly meeting of the Academy was held Monday evening, July 21st, Vice-President Harkness in the chair. In compliance with a request of the Society, Dr. Kellogg read a paper on the life and services of the late John B. Trask, M. D., a life member, and one of the founders of the Society. W. N. Lockington read a paper on some of the crustacea of this coast.

The following paper was read by Dr. A. W. Saxe, of Santa Clara, on the subject of a Remedy for Grape Mildew.

This grape mildew (oidium) is familiarly known to all microscopists, its ravages are too well understood by all vine growers, to require any specific description. The object of the following paper is to point out a simple, economical treatment of the vine by which its ravages may be averted.

In the winter of 1868, having suffered the loss of all my grapes, in a small vineyard of 150 vines, from mildew, I cast about for some remedy for the disease. My neighbors were using sulphur, and were to some extent successful in preventing the disease. I had used it also, but found that unless three successive applications of this sulphur were made, the first on the opening of the buds, the second on the falling of the blossom, the third when the grapes were about one-third grown, there was no certainty of success. And that often after the utmost care the grapes were so far injured as to be of only second or third rate quality.

The fact that wheat growers uniformly applied a solution of bluestone (cup. sulph.) to their seed before planting to prevent smut, suggested to my mind the use of this agent in combating the mildew upon the vine.

My vines being at that time some ten years old and covered with rough loose bark, I had them cleaned immediately after pruning, by a small triangular steel scraper, and then a solution of bluestones, four pounds to five gallons of water, applied with a swab to this dormant fruit buds and to the entire body of the vine. Then after carefully spading the ground, no further attention was given to the vines during the season. The result was an entire absence of mildew and perfect grapes.

From the above facts to the present season I have omitted or neglected to apply the bluestone three seasons—1873, '76, '78; the result has been diseased vines and no grapes.

Last February, after my vines were pruned, I employed a man to clean out the vineyard and apply the bluestone solution. He did his work faithfully, but omitted to apply the solution to one row of 12 vines of the Black Frontignan variety. At this date, July 1st, all the vines are healthy except this row, which is now exhibiting this curled, everted leaf so significant of the disease, and I have applied sulphur, but with little probability of saving the fruit.

The above is a concise narration of my experience and observation, in regard to the use of the bluestone for preventing mildew upon grapevines.

Young healthy vines having smooth compact bark, are comparatively free from the disease. But after six or eight years of age the forks of the vine become filled with decayed vegetable matter and atmospheric dust, and unless this accumulation is removed it affords a nidus in every plant for the lodgment and subsequent growth of the oidium spores.

Vineyards remote from public highways, on mountain sides, or elevated localities, where the atmosphere is free from dust, suffer least from the encroachments of the disease. But in any locality, having been once introduced it remains, unless it is destroyed by the use of sulphur or bluestone.

My observation confirms me in the belief, that one application of the solution of sulphates of copper to the dormant grape bud is a more complete protection than sulphur however often used, or any other agent heretofore used for the purpose. That as it can be applied at a time when all parts of the vine are accessible, and one application is efficient, there is a great saving of time and expense in treating the vines. That however efficient the sulphur may be when it can be applied directly to the fungus, it cannot be effectually applied after the expansion of the foliage of the vine, except by some other method than that usually employed.

I am satisfied that healthy vines may become diseased after some development of the foliage by proximity to diseased ones, and hence the necessity of making thorough work and leaving no diseased vines to the windward of those treated.

It is needless to say that the evolution of the strength above certified is quite destructive to the foliage of the vine.

The application of the solution to the vines, while there are yet two months of moist weather with occasional rains, keeps the salt in a state of solution more or less of this space of time, and is constantly acting as a protection to the vine.

It is desirable that the above facts should have the widest publicity before the next period of treatment of the vine, as they are quite important to the vine-growing interests of California.

SOME of the Paris streets which have Bonapartist names are to have them changed, and one will be called Lincoln.

News in Brief.

The Spanish Cortes will soon abolish slavery in Cuba.

EASTERN advices report the outlook of trade as generally good.

The people of Cincinnati have been defrauded by a crooked election.

A VIOLENT hurricane last Sunday in the Adriatic damaged 20 vessels.

Nihilists have burned 17 houses at Katlaoff, on the Dnieper.

At Sierra City, a few days ago, the thermometer marked 101° in the shade.

THE increase of revenue receipts for the year ending June 30th, 1879 is \$2,820,740.

TENNESSEE being penniless, Memphis will be obliged to obtain relief from other cities.

THE Bonapartist party of France invites the secession of those who do not support its head.

THE members of the French Corps Legislatif are quarreling over Jules Ferry's educational bill.

THERE is a rosehush in Los Angeles which has borne over 3,000 roses during the present season.

THE temperance question has been solved by the burning of Leight's brewery at East Williamsburg, N. Y.

THE 31st anniversary of the independence of Liberia was celebrated at Savannah July 28th, by 3,000 people.

COONS are making much trouble for ranchers along the American river, especially those who are raising melons.

THE present government of Italy have sought the aid and protection of Garibaldi, who is the D. K. of that country.

THE Free library bills have at last been paid, and the sum of \$24,000 will be used this year for library purposes.

THE Evangelists, Moody and Sankey, had a very successful meeting Sunday evening, at Cooper Institute, New York.

A PROPOSITION has been made to exhibit a trick monkey on the Kansas Pacific railroad for the amusement of the passengers.

THE Congressional Committee on Trade and Industry, are busy at Chicago trying to find out what causes dullness of trade.

AMERICAN vines are to be largely introduced in France, in consequence of the ravages of the phylloxera in French vineyards.

LAST Saturday a destructive storm in Monongahela and Alleghany valleys destroyed, at Petrolia, \$200,000, many people being left destitute.

SHREVEPORT has quarantined against New Orleans. The situation at Memphis is unchanged. Great fear of the yellow fever exists everywhere.

M. de LESSEPS is astonished that Americans oppose his Darien canal scheme, since he offers to make Gen. Grant honorary president of the company.

COUNT ZICHY, Secretary of the Hungarian Ministry of Public Worship and Instruction, having been accused of corruption has tendered his resignation.

THE Grand Vizier of Turkey has resigned and his office has been abolished, the office of Premier and Minister of Foreign Affairs being substituted for the Grand Vizierate.

A MATCH game, for a hall and bat, was played last Sunday, between the Lone Star Club, of Visalia, and the Farmersville club. The former made a score of 33 and the latter 22.

HINTS ON NATIONAL CULTURE.—We acknowledge receipt from E. Steiger, publisher, 25 Park Place, New York, a pamphlet entitled "Hints toward a national culture for young Americans," authored by S. S. Boyce.

This author seems to infer that "unless the United States adopts an improved system of educational training she will never be able to take her position as the first industrial nation; and that the growth of idleness, discontent and labor riots is to be stopped by supplying the children with the rudiments of a practical, useful knowledge," etc. There is no doubt about the value of an industrial education, but that alone will not put bread into the mouths of hungry families.

Hunger and not the lack of education is the mainspring of labor troubles. Give education, but afford opportunities to make that education available, and the evils complained of will be cured. The hook, however, is well worth perusal, although in our opinion it does not cover the ground. Its aim seems principally the advocacy of a national school system—a system which might perhaps be as successful as the Indian Bureau.

THE NEW ROUTE TO BODIE.—The Pioneer Stage line travel over the new road to Bodie, which is the shortest from San Francisco by 170 miles. The stages connect with the railroad at Milton. Passengers from here leave on the 4 P. M. boat for Stockton and leave Stockton at 8 A. M. the following morning, connecting with the stage at Milton at 9:30 A. M., and arriving at Bodie at 4 P. M. next day. The advertisement in another column gives the days of departure, and the agents, Messrs. T. J. Matteson and Edward Harrison, at No. 3 Montgomery street, will give all the information desired. Both time and distance are shortened by the new route, which is a desirable one to travel over, and the company are well provided with easy coaches and good stock, so the ride is one to be enjoyed. Our correspondent, Mr. Wheeler, recently passed over this route on his way to Bodie.

The Fairs of 1879.

The following is a partial list of the dates and locations of the agricultural and industrial fairs which will be held this fall on the Pacific coast. In order to make our list complete, we request Secretaries of all fair societies to send us the facts concerning their exhibitions as soon as the dates are fixed:

Mechanics' Institute fair, San Francisco, August 5th to September 6th
California State fair, Sacramento, September 8th to September 13th
Golden Gate District fair, Oakland, September 1st to September 6th
San Joaquin Valley District fair, Stockton, September 16th to September 20th
Southern California Horticultural fair, Los Angeles, October 20th to October 26th
Southern District Agricultural Society fair, Los Angeles, October 20th to October 26th
Sonoma and Marin District fair, Petaluma, September 22nd to October 4th
Santa Clara District fair, San Jose, September 22nd to September 27th
Napa and Solano District fair, Vallejo, September 16th to September 20th
Northern District fair, Marysville, September 16th to September 20th
El Dorado County fair, Placerville, September 15th to September 18th
Monterey County fair, Salinas City, September 30th to October 3d
Siskiyou County fair, Yreka, October 1st to October 4th.

ANDERSON SPRINGS.—These celebrated hot and cold sulphur, iron and soda springs are situated in the midst of a pine and spruce forest, in Lake county (a distance of 19 miles from Callotago, and 10 miles—by an excellent road—from the Great Geysers; the nearest and most accessible pine grove, to San Francisco and Sacramento), beside a living trout stream and surrounded by splendid mountain scenery; in the most invigorating and health-giving climate in the State. Good attention is given to the health and enjoyment of all visitors. Prices are very reasonable. Address Anderson Springs, Lake Co., Cal.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All now novelties find a place at this wonderful resort. Prices remain as usual.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So he sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

PRINTER'S PROOF PRESS, complete and in good working order, for sale at this office, at the low price of \$30. Call and see it.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

Mining & Scientific Press
Patent Agency.

PATENTS obtained promptly; Caveats filed expeditiously. Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The ablest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

DEWEY & CO., Patent Agents,
Office—202 Sansome St., N. E. Cor. Pine, S. F.

A. T. DEWEY, W. B. DEWEY, G. H. STRONG.

The Mechanics' Fair Daily.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the TENTH VOLUME of the MECHANICS' FAIR DAILY during the FOURTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Tuesday, August 5th, 1879.

It will be of handy size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it gratuitously at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive newspaper and special advertising and printing privileges of the exhibition.

Our nine previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our Coast.

Advertisements will be inserted in first-class style at very reasonable rates. Orders should be given early.

DEWEY & CO., Publishers.

Office, MINING AND SCIENTIFIC PRESS, No. 202 Sansome street, N. E. corner Pine, San Francisco.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in subdivisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Numa Mining Company.—Location of Works, Humboldt County, Nevada.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 1) levied on the 13th day of June, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. of Cert.	No. Shares.	Amount
Blasdel, E. W., Trustee.....	27	500	\$ 15 00
Blasdel, E. W., Trustee.....	28	500	15 00
Blasdel, E. W., Trustee.....	31	500	15 00
Blasdel, E. W., Trustee.....	47	500	15 00
Blasdel, E. W., Trustee.....	48	107	balance 5 00
Brown, George A.....	42	500	15 00
McKusick, H. J.....	44	1000	120 00
Pierson, Wm M., Trustee.....	53	2500	balance 75 00

And in accordance with law, and an order of the Board of Trustees, made on the 13th day of June, 1879, so many shares of each parcel of said stock as may be necessary will be sold at public auction at the office of the Company, 328 Montgomery street, room 21, San Francisco, Cal., on the 11th day of August, 1879, at the hour of one o'clock p. m. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

DAVID WILDER, Secretary.
Office, 328 Montgomery Street, room 21, San Francisco, California.

Annual Meeting—Office of the Rocky Point Mining Co., San Francisco, Cal., July 23d, 1879. The Annual meeting of the stockholders of the Rocky Point Mining Company, for the election of a Board of Trustees for the ensuing year, and for the transaction of such other business as may properly come before it, will be held at their office, No. 314 Bush street, San Francisco, California, on Monday, August 18th, 1879, at two o'clock p. m. of that day. Transfer books will be closed on Monday, August 11th, 1879, at 12 o'clock m.

T. L. BIBBINS, Secretary.

EMILE BOESCH,

LIFE-SAVING RESPIRATOR
Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

STEEL CASTINGS.

From 1-4 to 10,000 lbs. Weight.
True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address
Chester Steel Castings Co.
Works, Cheeter, Pennsylvania. 407 Library St., Philadelphia

THE CALIFORNIA POWDER WORKS.
MANUFACTURERS OF
Sporting, Cannon, Mining, Blasting and
HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.
PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.
JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street. - - San Francisco, Cal.

RUSSELL'S AMALGAMATOR.
Patented June 25th, 1878.

SAVE YOUR GOLD
And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Rifles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.
Capacity, 30 to 60 tons per day, according to size. For further particulars apply to -
J. MORIZIO, Gen'l Agt.,
Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

Pioneer Plating Works.
MANUFACTORY OF
Silver Plated Amalgamating Plates,

For Quartz Mills and Gravel Claims. Are prepared to furnish any size Plate promptly and satisfaction guaranteed. Old Copper Plates purchased, Plated or the Gold Extracted by the most complete process, at small cost, and the copper saved.

FRANCIS SMITH & CO.,
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

VOLUME XXXIX
Number 6.

Prescott, Arizona.

We give a picture of Prescott, the capital of Arizona, taken some years ago, more for the purpose of showing the general features of the surroundings than to delineate the city as it is. The growth of the city is quite rapid, and this fact must be borne in mind when examining the illustration: Prescott was thus named in honor of the eminent American writer, and standard authority upon Aztec and Spanish-American history. The site thus selected is near the intersection of the 34th parallel of latitude with the 112th of longitude. The streets all run with the cardinal points of the compass. A like excellence of judgment was shown by its founders in naming the streets after persons identified with the former or present history of the Territory, such as Montezuma, Cortez, Marina, Alarcon, Coronado, Whipple, Aubrey, Leroux, Walker, Laird, etc. Its broad streets reach out from a central plaza, giving ample space, and avoiding that density of structures and population which so jeopardize the sanitary condition of many of our large cities. The buildings are of stone, brick, and pine.

Prescott is really a home-like place, and would be considered so anywhere. Climate requires one either to live in or out of doors. In Prescott, with high altitude, cool, even raw, chill evenings, its sub-Alpine flora, and the other indications of a decidedly temperate region, one must really live in doors. In Tucson the reverse is almost true. There are no adobes here. There are a few log dwellings—reminiscences of earlier days; but the large majority of buildings are of frame, some business places being of brick, with a few residences also. Really, and without flattery of any kind, Prescott is a very attractive town. It is situated in a small valley, or basin, surrounded on all sides by more or less elevated mountain ranges. In the center of the town is a large plaza, now bare, but which is to be occupied at no distant day by county buildings, for which \$60,000 has already been voted. Yavapai county, of which Prescott is the county seat, is, it must be remembered, not only the largest in area, but the best populated of the five into which the Territory is now divided. It claims about fifteen thousand inhabitants.

The vicinity of Prescott offers ample facilities for grazing purposes. The hill and mountain sides, far up to the pine and cedar belt, are covered with the hunch grass—quayotto or black grama. The soil is more moist than to the south or north. It is arid and desolate in both directions to some extent. Sheep do better in the vicinity of the Bill Williams mountains, portions of the Rio Colorado-Chiquito, the famous San Francisco mountains and the vicinity of Mineral Park and the Hualpays than in the immediate vicinity of Prescott. Thereabouts the cattle ranges are good and ranches are quite plenty. Timber—pine in plenty, cedar and dwarf oak to some extent—is found everywhere. This portion of Arizona and north of it will be the chief source of timber supply.

On the northern spur of the Bradshaw or Silver range, one of the best metalliferous formations of northern Arizona, Prescott sits in pleasant security, expecting prosperity, and believing herself the favored town of this wonderful Territory. Its altitude is 6,318 feet above the sea level, and a stranger soon appreciates the fact. The landscape is as marked and massive, but yet its features are smaller and must be taken more in detail, than in southern towns. There is not the same marvelous scope of vision, and hardly as many wonderful effects of color-tone and distance. Still, the artist's eye may readily find materials for captivating pictures, even if he cannot make the range so large as at Tucson or in the valley of the Santa Cruz, where the hold and well defined peaks and serrated summits of the Santa Ritas look down in lusty beauty on the one hand, and the

bald, hold outlines of the San Coyetano or Atascosa mountains hem in the other. Towards the north the little plain or plateau on which Prescott nestles opens into a broad sweep of plain, on which Fort Whipple is located, and across which the vision takes in on the east the saw-like summits of the Pista range, with the hold outlines of Granite peak to the west thereof, while still further to the south and west are blue outlines of the St. Marie mountains, from the midst of which Hopo Peak lifts its hold head in the hazy distance. To the north and east again the eye glancing over Prescott plains rests on the sweeping lines of the Black Hills, whose southern extremity comes down almost to the town limits on the east. Overtopping these and at least seventy miles distant, in a direct line, can be seen the San Francisco mountains, snow-covered for several months in the year. To the south the view is almost a closed one, as the Bradshaw ranges rises holdly in that direction. Looking down over the town, as if protectingly, towers a singularly bold peak or rock formation known as Thumb Butte. It takes its name from a huge pile of rock on its northern end, which, looking down on the village below, appears to be a

of striking hues, while the deep, serrated sides of the range loom deep shadows wherewith to tone the pictures. In the midst of them, closs to the ground, hroods the peaceful town.

Bucket Shops.

The "combination system" of investment in stocks, urged upon the public, is nothing new except in name. The "system" modestly requests the investment of an enormous sum of money, in contributions ranging from ten to one hundred dollars, upon no other security than promises of large returns from small investments. Here is a direct attempt to inveigle the poor and those in moderate circumstances into a golden snare which has, and always will, result in loss or ruin, to nearly all who are attracted by it. Upon the ground that "wealth is strength" you are plausibly invited to combine your respective small amounts into one grand pool, in the hands, and under the exclusive control of irresponsible parties, to be operated with according to their discretion; to hull or

The Sun as an Electric Focus.

The problem of the source whence the sun derives its heat and light is perhaps no nearer a practical solution now than it was a hundred years ago. It is true our knowledge of the constituent elements of the sun has increased, but that knowledge is only abstract. It has been contended that the sun is a burning mass, which, in the course of time, will "burn out," and leave the planets dependent upon it, uninhabited—dead. All of the combustible elements of this earth are said to be stowed-away sunbeams. The coal so largely used as a steam generator and for economical purposes, a product of the sun. Concentrated sunbeams, the hidden heat of which has been brought forth by the industry and genius of man for purposes of comfort and utility. Some writers have declared the sun to be pure fire, not fed by any supply, while others declare it to be the rendezvous of comets, the absorber of dead planets.

Prof. Proctor estimates that in each second of time the sun distributes as much heat as would be produced by the consumption of eleven thousand eight hundred millions of millions of tons of coal. He further estimates that if the sun consisted entirely of coal, burning at this rate, it would burn out in less than 5,000 years.

If the sun derives its combustion from material within itself, it would seem as if there would be some diminution, and since Herschel looked at the orb and calculated its conflagration, such an enormous waste of gases would surely have been noticed by succeeding astronomers whose calculations are quite exact. But the light and heat of the sun is not on the wane.

The latest theory is that the sun is an emitter and receiver of electricity at one and the same time. It is contended that there is a mighty outpour of magnetic currents from the north and south poles of our planet, and that these currents meet and form a complete circuit, the sun being the point of meeting, as it is with the earth, so, also with all the other planets, only the outpour is greater, or less, according to size. Focality produces luminousness, and the currents are sent back to the planets and their satellites in proportion to their respective wants. Scientifically put, the new theory is that the planetary system is a vast magnetic-electric machine, or "generator," the planets being permanent magnets, which, while in motion, generate electricity enough for their own light and heat, with some to spare, the sun is the carbon point" where all these currents meet and become luminous. Thus, the sun, instead of depending on the combustion of coal meteors or other fuel or friction, or "contraction" of its own surface, which would soon leave us in darkness, is dependent upon the electricity generated by the planetary system for its light and heat. This disposes of the non-eternity of the sun as a light-bringer to planets, and hurries for an indefinite time Proctor's melancholy theory that the earth will breathe its last and give up the ghost as a life-producing and life-bearing body at a day somewhat too early for happy contemplation. It gives a possible solution of another vexed question, the origin of the aurora borealis, by assuming that when the electric currents are interfered with by meteoric or other bodies, the back-flow produces that splendid phenomenon. Altogether, the theory is worthy the attention of astronomers, who are as much in the dark about the sun's heat and light as unscientific persons.

THE Central Pacific engines burn between 55,000 and 60,000 cords of wood per year between Sacramento and Ogden. It costs from \$3.50 to \$3.75 per cord delivered on the track. It is all cut between Reno and Auburn.

A VEIN of coal 10 feet thick has been discovered in Cassia county, Idaho.

PRESCOTT, THE CAPITAL OF ARIZONA.

gigantic hand doubled close, and on the top of this closed hand there appears to be a huge thumb, slightly bent, the end of which lies toward the town. Behind this peculiar formation there is a small table land, across the south end of which are unmistakable evidences of a wall, used, without doubt, for the purposes of defence. There are some appearances left of approaches up this rock and of cave-dwellings on the top. As to the east and south of the town, a line of defense works, so irregular and broken as hardly to be followed, has been made out, it would seem certain that the sight of Prescott was also that of a town or post, once occupied by the people who cultivated centuries since the valleys of the Gila, Salina, San Pedro, Santa Cruz, the Rio Verde, Rio Francisco, the Colorado-Chiquito, Agua Fria, and other streams, leaving as proofs of their industry and skill the evidences of old towns at the Casa Grande and near the Tempe and Phoenix, on the Salt river, as well as many other signs of their extent and character.

The flora and timber of the neighborhood are decidedly those of the temperate zone. As he fits the altitude, there is a clear, cold, gray tone in the atmosphere, which lends a peculiar charm of its own to the surrounding landscape. The great pines which clothe the mountain sides almost to their tops fill the still night with that low, sighing wind-music that has such an indescribable though melancholy charm. The sunrise and sunset, especially the latter, drape the tall ridges and high peaks in a variety

hear the stock market or to put your money into their own pockets as they may think proper. "All the fools are not yet dead," is the cornerstone of their enterprise, and the foundation of their success.

If "wealth is strength," and a thousand people, with \$100 each, can do nothing in the way of speculating as individuals," what has become of the combined wealth of some of our best and most solid men? Drawn into this fever of speculation by just such fallacies, they now, from their dishonorable graves, cry out in warning to you, Beware!

You are assured of absolute success in your investments in their stock operations, a falser and more dishonest representation was never made in any of the gambling hells of Europe whence this "combination system" came.

It is incredible how any one can be deceived by this barefaced falsehood, with the certain knowledge derived from sad experience demonstrating the lie so plainly, that "he who runs may read." There is no certainty in any legitimate business, and even the probability of success in stock operations stands at zero.

The signs of the times indicate another struggle to bring disaster upon us, before preventive laws can be passed to drive these swindling fallacies from the State. If, dazzled by gilded lies, you invest in this thing, you will surely behold capital leaving the State—capital which can and should be kept here. The effort to keep it here is an easy one to make, the secret of it is "do not invest" in these swindles.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Ascent of Mt. Shasta.

[Written for the Press by J. G. LEMMON.]

Mt. Shasta is the most impressive peak known to travelers. The grand distinguishing features of Mt. Shasta, those which give it this pre-eminence, are not so much its lofty height of 14,442 feet, but first its entire isolation from other peaks, and second its majestic up-rise of nearly 11,000 feet from the midst of a heavily forested plain, broken here and there only by meadows of robust grasses and rich cultivable fields.

The group of lofty peaks in southern California—Whitney, Kaweah, Tyndall and King, though from 200 to 500 feet higher than Mt. Shasta, fail to strike the beholder as predominant peaks, because they stand on an elevated plateau 8,000 to 11,000 feet high, a plateau clothed with forests and easily reached by horsemen.

The plain around Shasta is only 3,567 feet high, from which the magnificent double cone arises over two miles vertically, in a line of less than ten.

Through the kindness of Gen. B. B. Redding I was invited to join his party for ruralizing in the vicinity of Shasta, during a portion of the heated term, including the Fourth of July. Himself and most of the party upon arrival at Sissons, at once sought their old haunts for fishing and hunting over on the McCloud river, leaving me to botanize at will.

Finding a party forming at Sissons for scaling Shasta and learning that the first days of July, before forest fires were raging were the best for views, I gladly left off searching copse and meadow for rare flowers and joined this party.

The ascent requires a day and a half. You go the first half day to a etated camp at the timber line and remain for the night. Early the next morning you leave horses and climb the peak, arriving at the monument some time in the P. M. The descent is made, the whole distance of 18 miles, back to the hotel by supper time.

On the afternoon of the 7th of July our party of eight started from the usual headquarters of tourists at Shasta—Sissons' hotel, in Strawberry valley. We were mounted on sure-footed horses and directed by an experienced guide. The trail led at first through a thinly-forested even plain for three miles, then gradually ascended over rough lava and conglomerate boulders to an upper parterre or bench several miles wide and surrounding Shasta on all sides. Here the common pine, with the white fir and Douglas spruce, that form the bulk of Californian forests, leave off, and the noble fir (*Abies nobilis*), of Douglas, often called from the color of its bark when broken "the red fir," occupies the plateau exclusively. This is, perhaps, all things considered, the most beautiful tree at all ages in the West. Trees of 5 feet in diameter and 150 feet high, do not depart from the graceful arrangement of their spray in youth, but still display their immense, horizontal, fan-shaped limbs in symmetrical, diminishing whorls to the top. On the upper limbs, erect and firm, stand the purple or yellowish cones, clothed with long, pointed bracts that depend from between the scales, causing the cones to resemble owls at roost on the tree tops.

Fringing the upper edge of this fir forest and running up the projecting rock-ribs of Shasta, are two more cone-bearers, found only on such elevations in this latitude—*Pinus albicaulis*, or the "white stemmed pine," and the *Picea Pattoniana*, or "silver spruce." Both these trees are often mislabeled; the first *Pinus flexilis*, the other *Abies Williamsoni*, but the former names have been established by the highest American authority after much examination.

The evening of our camp where timber and snow banks mingle, was clear and fine, inviting to study the stars in the brilliant canopy. Later, after all were under blankets spread over pine and fir boughs, the cold air poured down the sides of Shasta lifting blankets or piercing them so sleep was banished except from the mountaineers of the party.

At the dawn of daylight we were up and shivering around a large fire while swallowing a forced breakfast, made barely eatable by a tin cup of delicious coffee. Then selecting alpenstocks from a store at hand, we started up the smooth hard snow beneath which rumbled and ground an incipient glacier. Our course as indicated by the guide lay directly up the deep canyon of the broad inclined valley on the southeast side. There was no dodging the smooth, forbidding, snowy step by any zigzag approaches. Six thousand four hundred feet of vertical rise (over a mile and a quarter) must be made by about five miles upward grade. Does not that statement appal the reader? No wonder so few persons attempt to scale Shasta. Only about three dozen names are registered in the book prepared for the purpose and kept in a cairn of rocks near the monument.

A party, preceding us by a few days, failed to reach the top, though composed of stalwart hunters. Every season parties essay in vain to conquer Shasta. Ours was the first to succeed this year. Personally, I never had such difficulty in getting a foothold in climbing snow-clad peaks, or was so much affected by the rarity of

the air. Every few rods I was obliged to drop down on my face and rest a few seconds, a proceeding soon adopted by nearly all the party.

Arrived by slow, toilsome labor to about the upper third of the down-swooping canyon, the steeper snow face, shaded from the morning sun, was found nearly as hard as ice. We had to strike feet and pike repeatedly into the flinty slope, in order to make a half-inch ledge for the side of our nailed boots. Not a word was spoken. Questions as to direction, were asked of the guide, and answer returned by motions. Only the ring of iron-shod boots and resonant pike, with the hard breathing of your nearest companion, was heard. The inclination was about 25 degrees only from the vertical. Dropping to the surface now to rest was impossible. We could only keep to the steep incline by carefully keeping one foot and the pike in place. Below, the chasm yawned a full mile of threatening descent; above, a steeper mile stretched away to the sky.

And now I must make a humiliating confession. Being no longer the athlete I was before Andersonville, I am now no longer a daring cragsman and an undaunted mountaineer. Shasta has broken my spirit; from henceforth, he has substituted a contrary statement for my long-vaunted boast. Before fully aware of my condition, the guide called out, "Lemmon, you are giving out and pale as a ghost. Let me assist you." I feebly protested as I turned my course directly for a ledge of rocks at the right and distant about eight rods. But I could no longer make an indentation in the snow with my weak, trembling legs. My head, aching dreadfully for the last hour, now became dizzy and my eye-sight was uncertain. The brave-hearted, noble-spirited guide (let me call his name, Dick Hubbard) came alongside, cut with his hatchet notches in the ice for my feet, and, dizzy with exhaustion and fright, I tottered along to the splintered rocks and was saved.

The rest of the climb—about two miles—had many nearly level sections in it of a few rods, and also many a steep declivity of ice and crumbling scoria, as difficult but not so dangerous as the part described.

By 2 P. M., we reached the hot springs in the old crater. These are still rumbling and spouting series of *solfatara*, the vestiges of the monster crater, a mile across, out of which poured a stream of lava that now overlies the plain for 100 miles around, but disintegrated and forming rich soil for one of the noblest pine forests in the State.

Lying on the interior heated rocks to rest, we learned from our guide how John Muir and Jerome Fay passed a fearful night there in April of 1875, roasting and freezing alternately, an adventure which Muir subsequently so graphically portrayed in *Harper's Magazine*. It appears that a change to cold and storm occurred in the night, the snow falling thickly upon the adventurers, and melting by the warmth of the gas jets, with no pure heat to dry them off. Being short of food they were forced to return the next day though the terrific wind froze their garments stiff as sheet iron. Arrived at the base, they found their feet so frozen that histers formed all along the sides, and eventually they lost most of their toe-nails. Muir had to keep his bed for a fortnight, but the time was not lost to the lovers of grand and graphic descriptions.

On the way up I was deeply interested in the different features presented by the noble old volcano of Lassen, distant southward 70 miles, but so distinctly seen as to seem only 20 miles away. He rests upon the eastern side of an alpine, snow-covered plateau, 20 miles across. With those daring friends, Case and Larsen, I had with great difficulty botanized the whole of that region, including the lofty Lassen. Now I was soaring 3,000 feet above the monument of that peak while the whole plateau lay unrolled at my feet.

Arrived at the summit of Shasta, undoubtedly the most diversified and extensive landscape is presented that ever astonished human understanding. You seem standing on a pedestal, rising out of the bottom of an immense, hollow hemisphere joining the equally extensive, over-arching hemisphere of the sky by an irregular, waving line at the horizon. The optical illusion is perfect. You are not perched two miles above the general earth's surface, but only raised up to its level.

It is impossible for pen to picture the details of this landscape as we saw it on that clear, cool, still July day. Not a valley or plain, not even a near canyon was obscured by smoke or dust. The whole anatomy of the many-ribbed Sierra Nevada, curving its vertebra to the sun in the southeast, was disclosed. The many parallel coast ranges with white tipped spines rode rank on rank in the west. Between these monster skeletons reposed the yellow grain fields of the Sacramento valley. Eastward rolled wave on wave of noble forests, limited at last in the far horizon by the peaks of the Warner range, shutting out the Great Basin of Nevada.

Northward this forest gives place to treeless plains, to interior, alkaline lakes and broad, fertile valleys. Of peaks the list would embrace hundreds, including nameless snow drifts glinting on the distant Oregon Cascades, 300 miles away, and the well-known St. Helena, Hamilton, Lola and Tahoe peaks as far away southward in central California.

A dense dark bank lying along the western horizon beyond the coast ranges, told where lay the cloud-forming Pacific. Was ever grander, clearer, more picturesque scenery vouchsafed to mortal gaze?

The physical features of Shasta—the im-

mense, bld, extinct volcano on which we stand—are past description in one newspaper article, even if I had the ability. We can but briefly examine its double crowns of unequal heights; gaze down into their broken-sided craters; smell, hear, feel and see the hot, sulphurous gasee still escaping from the biggest crater; trace the out-cropping ribs of lava gaily striped with red breccia, black mica, gray trachyte and brown scoria, extending from crater mouth down to timber line; follow the still living glaciers between, in their slow, majestic march down along the track of their mighty predecessors in the old ages, these glacier heds now appearing like the smooth trail of monster serpents as they form the peculiar curving, steep-sided river valleys entering and bidding in the dark, evergreen forest on all sides; we can see all these visions, then come away from Shasta bearing with us glorious, ever-recurring, priceless memories forever.

The descent of Shasta is a speedy, and in our case, was a most enjoyable experience. Arriving at the top of the precipitous canyon, described on the way up, we prepared to slide down on the now softened snow, by passing a loop of baling-rope attached to a barley sack over our necks, allowing the sack to drop down in front, then sitting down upon the sack, for protection against injury to clothes—aye, and flesh, too, perhaps, if certain rocks known to be near the surface around yonder bend should be exposed by this warm afternooon sun.

Sitting down on the edge of the precipice, then removing the pike from the snow, away we dropped one after the other, skurrying along and swaying from side to side, swiftly down the long canyon. At once, as soon as the leader plunged off the precipice, he set up a shout of joy, which was taken up by each follower in turn, and soon a grand chorus of yells and cheers resounded all along the line. There were several collisions and upsets, which were instantly rectified, and one sharply-contested race. Friends at the hotel, 10 miles away, happened at the moment to be looking for us with the aid of opera glasses, and they declare that we shot down the whole mile and a half in less than half a minute.

It was noon next day before all the Shasta pilgrims became visible around Mrs. Sissons' dining table, exhibiting nearly every degree of exhaustion, blindness and suffering. Each had a story of special adventure to relate, and of peculiarly ecstatic enjoyment experienced, but the expression most often heard—the one that met with unanimous concurrence—was: "I'll never be so foolish, again, never!" But, dear reader, we were tired then, and so, perhaps, are you.

A few days afterward, a gentleman connected with the United States Coast and Geodetic Survey, conducted on this coast by Prof. Davidson, arrived at Sissons' with several stage loads of equipments for ascending Shasta and establishing a signal station thereon.

Mr. Sissons employed several experienced guides and about 15 stout Indians to pack the outfit up the peak, but their labor was to be much obviated by making a new trail up one of the rock ridges, avoiding the snow. Hence, hereafter, tourists will find the ascent easily accomplished. And now, my aches gone, bruises healed and clothes mended, while the old, snow-mantled, cloud-veiled monarch looms up yonder, loftier and grander than ever, because I know him, I join my predecessors in advising every lover of nature, if they would "see all the world," to climb the lofty cone of old Shasta. Sissons, July 20th, 1879.

Mining Along the Humboldt.

EDITORS PRESS:—From Wadsworth over the desert to the head of Humboldt sink, no discoveries of valuable mines have been made. But a few miles above this sink, at Lovelocks, fair mines are spoken of to the south in the first mountain range, but undeveloped, waiting for capital to work them. At Oreana, 12 miles more, are others of the same character. Ten miles more, at Rye Patch, other mines again appear only 12 miles south in the mountains, and have been worked, with good results, in a five-stamp mill, for some years, but are now shut down. Again, at Mill City, other mines appear, but entirely undeveloped, while from this point the very rich mines of Union City, 20 miles to the south, are reached. But 30 miles more, and one comes to Winnemucca, from which place, to the north 55 miles, at the head of Paradise valley, mines are worked, and are developing exceedingly rich. They are generally known as the Rose Mountain mines. They have but one mill running with 10 stamps, the Mount Rose, with Superintendent L. Rawlings, where the fine work done ensures the truth of the richness of the claims. Another mill, the Spring City, of 10 stamps, to be run mostly by water, is being built to begin work this fall—G. F. Williams, Superintendent. The Mammoth claim is the one more fully opened than the others, yet this is down only 70 feet, with a clear, distinct vein widening gradually to over five feet, all good working ore, averaging \$60 and \$70 to the ton. Other claims are being opened nearly as favorably, with increasingly favorable prospects.

Some 8 or 10 miles west of these are the Willow Creek mines. There immense developments are asserted; too great to be fully credited at once abroad, with true wide fissure veins, the largest of which is the Ethan Allen. Its tunnel is six and a half feet high by four and a half wide, all in the regular wide vein, and as-

saying at an attempted average over \$200 per ton. Twenty miles south, on the west side of Paradise valley, Mr. I. R. Whitaker has discovered and opened a very promising claim, descending on a regular quartz vein over 60 feet, four and a half feet across, and a saying some \$60 per ton. We could not visit all these mines, but from careful inquiry from different ones, as well as the owners, we believe these estimates below the truth.

Above Winnemucca 17 miles is Golconda, south of which, again a few miles, are different claims, the Harmony and others, which did promise well, but are lying idle for want of capital for their development.

Forty-five more and Battle Mountain is the depot for large and prospering mines. This is at the mouth of Reese River valley, on the east side of which, only 12 miles from the depot, at the foot of the mountain, are the Lewistown mines. The Starr and Grove, the Eagle and the Bettie O'Neil, are the principal ones; and, surely, on our carefully visiting their works and observing the clear, distinct and rich veins running into the sides of steep mountains, easily worked from tunnels, it did appear to us that tens of millions of dollars are here to be taken out. The veins are miles in length, and, most evidently, permanent. A fine town is here growing up.

On the west side of the valley, 18 miles from the depot, are the older mines of Galena, of which the White & Shiloh is the main one, opened and now very successfully worked under the superintendency of C. L. Strong, well known in Virginia and San Francisco. The process is that of dry crushing, bolting, roasting and leaching the sulphurets, and is a perfect success. The roasting is done in two of the largest revolving furnaces in the world.

Three miles south of Galena is probably the best worked copper mine on the coast; Superintendent, S. G. Truran. The ore is selected, broken, washed, and shipped abroad for smelting. Sixty miles up Reese river are the immensely rich mines of Austin. Thirty-two miles east of Battle Mountain, on the Humboldt, is Beowawc, with some few mines of which we did not become well informed. Twenty more miles is Palisade, from which a narrow-gauge railroad runs south by Mineral Hill mines to Eureka, of which more hereafter. Thirty-two more miles and one comes to Elko, a large, rather dull town, a county seat and the site of the State University, conducted only as an academy at present. But from here, by the stage line of Mr. Van Drielen, we turned northwest 68 miles to the town and mining region of Tuscarora. It is on the north side of a fine valley, 12 miles by 30 in size, and has a view of the whole, commanding a scene with the varied mountains around and beyond of unequalled splendor. But the mines of Tuscarora are its wonderful feature. The principal ones are the Argenta, the Grand Prize, the Independence, the Navajo, and the Belle Isle, with five or six others worthy of commendatory mention. We passed down the shaft of the first 500 feet and explored its different levels east and west hundreds of feet; then entered the Grand Prize by its connection with the first, and descended another hundred feet and out along its levels everywhere, wondering at the large amount of excellent ore brought to view. Immense quantities are quarried and stored away for hoisting to the mill, as they secure better facilities for working it. Four claims have only one 20-stamp mill for reducing the ore, but two other mills are being built.

The vein is distinctly bounded by walls, and varying in width from 6½ to 20 feet across, retaining all its richness as it descends. The whole vein may yield \$30 to the ton, but the better portion is selected, yielding \$70, \$80, and over \$100 the ton. From the Grand Prize, one rich gold-bearing slab was mined out in descending, which extended 30 feet deep, six feet wide, and from a thin line to four or five inches in thickness, which assayed \$105,000 to the ton, the whole being nearly one-half gold.

The Independence is an excellent mine, with its fine 10-stamp mill. From this mine we saw most admirable specimens of wiry, or hairy masses of pure silver, and compact crystals of ruby silver and of steeffinite. But all give the chief praise at present to the Belle Isle, working through the Navajo shaft and reduced in the Grand Prize mill. Its whole force of mining men is about 30, and its yield, as shipped, has been, the last month, first week, four days' work, \$23,000; second week, five days' work, \$29,000; third week, six days, \$39,000; fourth week, six days, \$40,000. These were not results of accumulation, but the simple week's regular work, and doubtless this general yield will be maintained for years, with regular milling facilities. We doubt if there is a more promising mining region in all northeastern Nevada than this Tuscarora. The population is perhaps 1,200, with a large proportion of families, generally American. The superintendents all appeared gentlemen, active and public spirited. The whole people appeared a worthy and intelligent community, as evinced by their being over 30 new subscribers for a publication of the real instructive character of the MINING AND SCIENTIFIC PRESS. We can well judge a community and each man by his treatment of an educative, scientific, useful paper like the Press. One who only wishes a daily for the news, and no more, or an Eastern paper because it is sharp, is not, we judge, a true American of soul and mind. We need for our mines and our farms, publications like the SCIENTIFIC PRESS and the RURAL PRESS, and all intelligent men should appreciate them. S. V. B.

MECHANICAL PROGRESS.

ELECTRIC BLOWPIPE.—At a recent meeting of the Academy of Sciences, M. Jamin submitted a new electric burner, which he also recommended to chemists and physicists as a blowpipe. Two carbons are supported vertically abreast, hinged below, and drawn together at the top by a spring. A current is sent up one, down the other, then round a rectangular circuit enclosing the two, and passing first round the first one by current attraction the carbons are drawn apart, and the arc appears at the top and descends gradually, consuming one or both carbons. When the action of the rectangle is sufficient, the arc driven beyond the points is like a gas flame, and M. Jamin receives it on a piece of lime, magnesium or zirconium, getting intense light. It is also so hot as to fuse the lime. For the electric light this burner has considerable advantages, since it has no mechanism and requires no preliminary preparation beyond a support and the carbon points. The size of the flame is almost doubled and the light is augmented. The new fuel is very powerful, and the quality of the light is far better, and the arrangement of the foci is more advantageous, the greatest quantity of light being directed downward, where it is wanted, instead of up into the air, where it is useless.

THIMBLE MANUFACTURE.—The process of making thimbles is described as follows: Bright new silver coins are reduced to ingots by melting in crucibles. They are then rolled into the required thickness and cut by a stamp into circular pieces of the required size. These circular disks are placed under a solid metal bar of the size of the inside of the intended thimble, which, moved by powerful machinery, descends in a bottomless mold of the size of the outside of the thimble, and presses the metal into the desired shape at a single blow. The remaining operations of brightening, polishing and decorating are performed by means of a lathe. First, the blank form is fitted with a rapidly revolving rod; a slight touch of a sharp chisel takes a thin shaving from the end; another does the same on the side, while a third rounds off the rim. The polishing is done by a round steel rod, which is dipped in oil and pressed upon the surface. Small revolving steel wheels, held against the revolving blank, pierce the indentations on the lower half and end of the thimble; the ornamentation is done by a similar process. All that remains to be done to the thimbles is to brighten and polish the insides, boil them in soap-suds to remove the oil, brush them up and pack them for the market.

BARREL CLEANING MACHINE.—A brewery at Monchain, in France, has been using for some time a patented machine for cleaning barrels. Four barrels are washed at once inside and outside. In the center of the machine is a shaft on which is a piece of metal so arranged that four iron hoops about three feet in diameter can be bolted on. These four hoops have each two sheet-iron plates mounted on pivots, and between these plates an attachment screw catches the barrels. Brushes fixed on springs are placed on a hoop outside the machine, and so arranged as to touch the four barrels at the same time. The circle of brushes is eccentric to the shaft. A reservoir under the machine has hot water for washing the outside of the barrels. A chain brush is placed in the interior of the barrel. The machine is worked by an ordinary pulley fixed on the main shaft. This latter carries the four barrels round, like the sails of windmill. The exterior brushes being stationary, produce a friction on the barrels which causes them to rotate on their pivots, so that two circular movements are obtained at the same time. The tables of the screws throw water on the barrels when they come to the upper part, so that they are continually kept wet.

ANTWERP EXHIBITION.—The *Iron Age* has received a copy of a circular issued by Mr. Stanislas H. Haine, of Antwerp, Belgium, giving information concerning the approaching international industrial exhibition at that place. Mr. A. Kaufman, 32 to 36 Park Place, New York, is authorized to accept and forward goods from this country, in the absence of any United States Commissioners, and will forward and return them free of cost, assuming personal responsibility for their sale or safe return. Heavy machinery or large and bulky exhibits will not be accepted on these terms, but all kinds of small articles adapted to the Belgian and neighboring European markets are desired, and can be exhibited with advantage. Mr. Kaufman will take much pleasure in giving such information as those who contemplate becoming exhibitors may desire. It is necessary, however, that immediate action should be taken, as only a short time now remains for forwarding exhibits.

SUPPRESSING THE INDUCTION DISTURBANCES IN A TELEPHONE CIRCUIT.—It is known that a secondary battery, composed of metal plates and sulphuric acid, allows weak currents to pass while stopping those of high tension. Prof. MacLeod therefore inserted a secondary battery of platinum plates between the line and the telephone, but this stopped both the induction and the vocal currents. When platinum wires were substituted for the plates, however, the induction currents were stopped, while the vocal currents could be feebly heard.

THE WERDERMANN ELECTRIC LIGHT.—A public exhibition of this new system of electric lighting took place lately at the Warf and Girder Yard, of Messrs. Rowson, Drow & Co., Southwark. Nine lights in the same circuit were kept going by a Gramme dynamo-electric machine of the old type, driven by a Rohey vertical engine and boiler. The light was very steady, notwithstanding the fact that the governor was disconnected from the engine. No shades or globes were used, except for one light in the office, and yet no unpleasant effect on the eyes was produced. The lamp consists of a hollow metal tube through which the carbon pencil is gradually fed up as consumed, being kept just short of contact with a carbon disc, the latter is balanced so as to fall down in case the pencil should not, from any cause, be fed up sufficiently to the disc. In this case, contact with the other pole, so that the current ceases to pass through that particular carbon, thus calling attention to the defect. Four inches of carbon are consumed in an hour, at a cost of 6d for 20 inches; and the nine lights only require 4½-horse power. In cost, therefore, the Werdermann light bears favorable comparison with other arrangements. The library at South Kensington Museum is now lighted on this system two nights out of the three a week that it is open; and Maj. Festing, R. E., the assistant director, expresses himself highly pleased with the result. —*Iron.*

ELECTRIC MOTOR.—Siemens & Halske, of Berlin, says the London *Echo*, have supplied a real novelty to the exhibition held in that city. It is an electrical railway, with three carriages, capable of carrying 20 passengers. The road is about 220 yards long, and the train travels at the rate of 10 feet per second, about seven miles an hour. A steam engine drives a dynamo-electric machine, and the current produced is transmitted to another machine which works the train. Deprez is exhibiting a model of his motor at Lille, and at the forthcoming scientific exhibition in the Palais de l'Industrie, at Paris, he will have a small train worked by a battery of 12 Bunsen cells. Possibly these are the beginnings of a great revolution, but we have a great deal to learn if that is ever to be brought about. Deprez hopes to be able to work an aerial propeller by his motor.

AUTOMATIC SPEED REGULATOR.—A contrivance has been invented by Messrs. Duflot & Duprat, of Bordeaux, for regulating the speed of machinery. It consists of a spindle to which rotary motion is imparted by the machine to which it is attached; on the spindle is fitted a sliding cone, and under the latter is a cross-head, bearing bent and counterpoised arms jointed thereon. When the spindle is revolved by the machine, the arms are thrown outwards at their lower extremities, but impinge upon the cone with their upper extremities, and by means of their varying friction on the cone, which increases with the velocity of the motion of the spindle, the speed of the latter is controlled, and its means and that of the machinery, with which it is connected by gearing wheels. —*Universal Engineer.*

NEW REVERSING KEY.—Dr. O. J. Lodge exhibited his new reversing key for electrometer work, which is preferable to the ordinary forms, as giving a high insulation, small capacity, and not requiring the hand to approach close to it to work it. It consists of four platinum wires, arranged in pairs, crossing one another; one pair crossing between the other two. These are the terminals and contact pieces of the key. The middle pair are supported by an endless silk thread, which runs on two pulleys, one of which is fitted with a handle. On turning the handle to right or left, the two middle wires are brought into contact with one or other of the two outer wires, and the current reversed at will. The whole is inclosed in a metal box. —*Physical Society, London.*

SAILING ON THE RAILS.—The Sioux City (Iowa) *Journal* says: Mr. John McMillan, the enterprising roadmaster of the Sioux City and St. Paul railroad, came here a short time since with his hand-car rigged with canvas, sloop style. The experiment of sailing cars on railroads seems to be a new departure, and the success attending the trial was well marked. The car has been in use about two months, and gives perfect satisfaction, having made, with moderate breezes, upwards of 18 miles per hour, and with its "leg of mutton" sail can sail close up to the wind.

LARGE IRON MILL.—John Brinkerhoff erected an iron mill in Albany, N. Y., in 1807. The operations of the mill were confined to converting Russia and Swede bar iron into plates, which were slit into narrow strips and these cut to the required length and made into nails by hand. This was the origin of the present large works of the Albany and Rensselaer Iron and Steel Company, which now employs 2,000 hands and pays out \$1,000,000 annually in wages.

NEW TYPE WRITER.—A new type-writing machine has been invented by Hansen, of Copenhagen. The aim of the inventor was to simplify the mechanism between the keys, which are pressed by the fingers, and the device which directly effects the imprint. The keyboard is abolished, and a semi-circular copper cap, over the circle of type-arms, made to do the work. By means of a rod, this cap connects with each arm with a single spring-push button.

SCIENTIFIC PROGRESS.

Iron into Fine Steel without Fusion.

Various processes are at present known for converting cast-iron into steel; those most in use being the Bessemer process, which consists in refining by contact with the oxygen of the air, and that known as Reaumur's process, which acts by means of reaction, and which has been greatly improved by Siemens, Pierre, Martin and others. Ingenious as all these processes are, none of them have yet yielded—nor can they ever yield—anything but imperfect results; the products in all cases consisting of compounds which are intermediate between true pig-iron, cast-iron and steel. For the purpose of getting rid of these defects, and of improving the quality of the metals, they are maintained for some hours at a red heat, in the middle of a mass of charcoal, over which is slowly passed a current of nitrogen, carbonic oxide, and various gaseous hydrocarbons. Wood, charcoal, peat, coke or any kind of vegetable matter, well dried and heated to a temperature of about 122° Fahr., is plunged into some hydrocarbon, such, for instance, as schist oil, which has been heated to the same temperature. Under these conditions, the liquid is absorbed by the carbonaceous substance in the proportion of from 12% to 15%. A pile is then formed of alternate layers of here of Bessemer metal, Martin iron or other product resulting from the refining of pig-iron, according to one or other of the processes above referred to; the whole is placed in the receiving apparatus, which consists of a kind of rotator of any shape, heat being applied gradually until the iron reaches a red heat. By these means, the excess of oxygen contained in the vegetable substances forms an oxide of carbon, by combining with the vaporized hydrocarbon, and the nitrogen assists in the formation of ammonia, so that the metals are surrounded by the gaseous compound which is recognized as being the best for their conversion into finished steel or cementation steel.

PLAYING BALLS.—India-rubber has been very largely employed of late in the manufacture of playing balls. These are made either solid, inflated, or self-inflating, and are used for a variety of games. The majority of the solid india-rubber balls, until very recently, were manufactured in Germany, but an English firm having acquired the secret of their success, a very large portion of the trade has reverted to this country. All description of india-rubber balls, with the exception of foot-balls, are vulcanized in strong iron molds, cast in two sections, and turned perfectly true on the inside; a number of these molds, when the rubber has been inserted, are usually secured together by one pair of clamps. The secret of the German method of manufacturing solid india-rubber balls consists in rendering the interior of the rubber porous, while the outside is perfectly uniform and smooth. The object of this is not only to make the ball much lighter, but to make it appear more elastic, and thus impress the uninitiated with an idea that they are manufactured from a better quality of india-rubber than they actually are. To produce this effect, the following ingredients are mixed together: 20 lbs of African ball rubber; 1½ lbs red lead; 46 lbs vulcanized (hect rubber) crumbs; 46 lbs vulcanized dark compound crumbs; 6 lbs salt, wet sawdust, or other substances capable of rendering the material porous by expansion when subjected to a high temperature. Total, 129½ lbs. The mixture is placed in crumbs in the molds, a solid wooden ball being used as a sort of kernel or center for each ball.

SILICIURET OF IRON.—The London *Engineer* reports that the French *Société d'Encouragement* has undertaken to examine into the uses that can be made of the new compound, "siliciuret of iron." An ingot, weighing about 3 kilograms (6.6 pounds) was sent to the Society by Prof. J. Lawrence Smith, having the following properties: Color, like platinum; specific gravity, 6.5; easily broken with the hammer; does not rust in the air; is not corroded by concentrated nitric acid, and is scarcely attacked by any reagents except fluohydric acid and by fusion with alkalis at a red heat. As a substitute for the rough-and-ready mode of testing iron and steel with the hammer, Mr. Hering proposes an electro-magnetic test. The pieces to be tested (wire, rods, bars, etc.) are passed through a magnetizing helix, when, if any break in the continuity of the fiber exists, the same may be detected by means of a magnetic needle suitably mounted on a block above the helix through which the test pieces are drawn.

DRAWING IN SCHOOLS.—The report of the judges on the school drawings lately exhibited at Boston, from various towns of the State, says that there is no feature of the exhibition this year so pronounced as the "systematic educational treatment of drawing in public schools, to make it useful as a preparation for the practical duties of life, as well as to employ it as an implement of education whereby knowledge of other studies may be acquired, rather than to consider it as an ornamental study only, of little practical importance. It is a triumph for drawing as an elementary branch of education, that all mere picture-making has been abolished, and a thing of work having industrial aims and means substituted for the thing of play that drawing used to be."

UTILIZATION OF EXHAUST STEAM.—According to the invention of Mr. N. W. Ericson, of Stockholm, he lets steam of higher pressure, or higher temperature, or both higher pressure and temperature than the pressure or temperature, or both, of the steam which is to be used in a steam-engine or for any other purpose, pass into an apparatus for the suction and compression of elastic fluids, in order that the said higher or stronger steam may in such apparatus act as the suction fluid to the said spent steam; this suction and compression apparatus is further connected with the apparatus wherein steam is to be used in order that the spent steam may to a greater or less extent be drawn into the suction and compression apparatus when the acting or higher steam passes through it. The mixture of the acting or drawing steam and the spent steam passes through the delivery pipe of the suction and compression apparatus (and its continuation, as required) either to the place where the thus compressed steam is to be used, or else first through an apparatus containing saturated steam, or water, or in so near connection with water that the steam if in a superheated state becomes more or less saturated or lowered in temperature, or else into an apparatus wherein the steam, by cooling, is rendered liquid, and the heat thereby given out is used for generation of fresh steam. This later apparatus may be the steam boiler in which the acting superheated steam is generated, or another steam boiler or vessel. The suction and compression apparatus may be any suitable section and compression apparatus, such as an annular or other jet apparatus.

SPONTANEOUS GENERATION.—Another contribution to the spontaneous generation controversy, favoring the germ theory, has just been published by Prof. Tyndall, in a paper to the Royal Society. He reports that he took with him to the Alps during the past summer one hundred flasks of infusions, 50 of turnip and 50 of cucumber, that had been prepared in the laboratory of the Royal Institution, and carefully sealed. Of these 20 were broken in transportation, and were found to be swarming with organisms. Another lot was opened in an atmosphere in which saw-dust had been shaken up, and was soon turbid with organisms; others were found to be infected by the proximity of a cascade of water derived from melting snow; while others that were opened in the pure air of the mountains were found to remain clear and uninfected. These results of Prof. Tyndall are entirely confirmatory of his previous experiments and announcements, in which he has always taken strong ground against the hypothesis of spontaneous generation advocated by Bastian and others, and has maintained the view that the origin of the swarms of organisms that make their appearance in decomposable animal or vegetable matter must be explained upon the supposition of infection from without, through the direct instrumentality of the air bearing the germ of these organisms in contact with the medium suited for their development. Tyndall, in the paper above referred to, places himself again on record as an opponent of spontaneous or non-parental generation.

ARTIFICIAL FUEL.—The invention of Mr. O. Hassel, of Heidelberg, Germany, consists of the manufacture of artificial fuel in the form of bricks or blocks out of peat, coal dust and other combustible materials in combination with sea-grass, sea-weed, sea-fan, or similar vegetable substances, and in combination with a coating of pitch or other suitable material. One or more of the above-named vegetable substances is or are hoiled in water to a jelly, which is then carefully mixed with the combustible material in a powdered state that has to be formed into artificial fuel until a pasty mass is obtained. The mixture is compressed in molds of suitable size into bricks, which are dried in the open air. After the bricks have sufficiently hardened the same are furnished with a coating of pitch or other suitable material to form a strong protecting surface against atmospheric influence.

DEVELOPMENT OF MINING INDUSTRY IN SPAIN.—A Franco-Spanish Company, the *Société Generale de Industrie Minérale*, has lately been formed for giving an impetus to mining enterprise in the Spanish Peninsula. They inspect and report upon mines, furnish various ores with a correct analysis (by arrangement with the School of Mines), and certificate of origin, and represent manufacturers of mining plant, which they push in various ways. Besides having a staff of agents in the principal towns, they have lately opened a permanent exhibition at Cuinta de Goya, Madrid, where the machines of English, French, Belgian and German makers are to be seen at work. The managing director is M. Ludovic Denis de Lagarde, who has lately resumed his office of consulting engineer to the French Embassy in Spain.

A NEW PROCESS OF GLAZING.—A new process of glazing has been introduced by which putty may be altogether dispensed with. Vulcanite is the substance that is to take the place of the old material. The window sashes under the new system are to be so arranged that the glass may be fixed into the grooves prepared for it, and, coming into contact with a strip of vulcanite attached to the frame, the glazing is complete. Any unskilled workman can fix the glass, and, when fixed, there is no putty to perish under the action of the atmosphere.

The Mining Share Market.

Without what may be termed a "booming" market, the past has been a satisfactory week to dealers in mining shares. After a season of depression, with sales slow and limited in extent, the market gained animation and strength at the very end of the week. Monday came and with it an incisive, sudden and unexpected upheaval, the north end stocks being especially buoyant. Chippers in hastened to realize, this being the first opportunity that had offered for a long time to make a profit, while short sellers, alarmed at the prospect, lost no time in filling outstanding obligations, a combination of movements that served to keep life in the market for several days after. Indeed the week closes with great activity and a cheery outlook. On Wednesday there was a lively call at advanced figures for Comstock shares, the demand reaching to nearly every standard stock from Utah to Silver Hill. As there have been but few Eastern orders since the June collapse, these purchases must have been mostly on home account, disclosing a growing confidence among local operators in this class of securities. But how to interpret these movements it would be difficult to say. The stock manipulator, like the oarsman, looks one way when he pulls the other. Stocks may be put up on their merits, through improvements occurring in mines or through the efforts of insiders who, having discovered the worthlessness of the mines, may be desirous of getting out. The Comstock sphynx sits in the Washoe deserts, mysterious and dumb, a puzzle to all save the keepers of the oracles themselves. Outside worshippers are at a loss to know whether it is coming or vanishing—a stern reality or only a myth. There is evidently a growing belief that important developments are about to transpire at more than one point along the great ore channel. What serves to strengthen this impression is the close personal attention that Mackay and Fair are just now giving to operations there. These men are not apt to devote themselves individually to this sort of work, unless some important revelations are expected and even imminent. At any rate, this is the construction put upon their constant presence in the lower levels of certain mines of late. Then, too, the knowing ones are generally beginning to stand in to the support of the old favorites, which also seems significant of the early approach of the good time coming. We trust it will not this time prove a failure, nor be much longer delayed. At the very end of the week the Comstocks, with one or two exceptions, closed stiff, while Bodie and other outside stocks were a little off. This class of mines are, however, generally looking well, and with the opening of new ore bodies, their shares would quickly respond in higher prices.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ITEMS.—*Dispatch*, Aug. 2: The Gray Eagle mine is being thoroughly prospected. Five stamps of the Empire mill are being run on rock taken from the mine as a test. The Victoria mine, south of the Empire, is also being prospected by San Francisco capitalists.

Downs.—*Lehigh*, Aug. 2: The new double-compartment shaft is down 200 ft. and connection made with the old shaft. Ventilation is now good. In the Lincoln, running drifts by contract system is the work in hand. The mill is running. The Potomac, between Amador City and Plymouth, is inactive, with the exception of keeping down the water. The Maryland continues to work a small force of men.

BUTTE.

BANNER MINE.—*Mercury*, Aug. 1: C. W. Keeney, Superintendent of the Banner mine, went to San Francisco Wednesday, taking with him 33 pounds of quartz gathered from the old tunnel run by McSmith and Sparks in '92. Old prospectors and miners who saw the rock, estimate its value at \$130 a ton on the dump.

CALAVERAS.

CONGO QUARTZ MINE.—*Chronicle*, Aug. 2: This mine is situated in Negro gulch, near Leavitt's ranch. The new shaft has reached a depth of 100 ft. The ledge, which showed very wide on the surface and was somewhat broken up, has narrowed down to a solid, well-defined vein four ft thick, all carrying gold. Good judges estimate that the ore will average \$30 per ton, taking the entire ledge as it comes.

Principle.—The principle over-shot wheel is to be built to run the hoisting gear, and the erection of a 20-stamp battery is to be commenced immediately. The Champion is looking better than at any other period in its history, and the mine has now been thoroughly prospected to the depth of 500 ft.

EL DORADO.

ITEMS.—*Democrat*, Aug. 2: Last Thursday the St. Lawrence mill and mining company closed a sale of their fine 30-stamp quartz mill and hoisting works to the Placerville gold quartz (the old "Pacific") mining company. This is the finest and most complete quartz mill property ever put up in this county. It will be at once removed to the mining ground of the purchasers, on Pacific hill, just south of this city.

MONO.

TIOGA DISTRICT.—*News*, Aug. 2: Tioga district is situated about four miles north from Mount Dana, and adjoins the south line of the Bodie mining district, and in a direct line is 25 miles distant. There are now some 400 men taken up principal among which are the Asherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tiposad, on which work has been done beyond stripping the ledge cropping out on the surface, which can be traced 1,500 ft in length; the Highrock, adjoining those mentioned above on the west, has a shaft down 22 ft, following a footwall, and in ledge matter, assays from which run from \$40 to \$200 per ton, mostly in silver; the Industry adjoins the Bevan on the east, and shows fine, large croppings. The formation of the country is porphyry, mixed with quartzite, which is inclosed between well-defined walls of granite, seeming to form a barrier to the outside rock. There can be traced from camp, with the naked eye, a well-defined mineral belt extending north a distance of over two miles, and south one and one-half miles.

Lucky Rodge.—*Standard*, Aug. 1: This mine is on Peak hill, a short distance below and parallel with the Asherton mine. The ore is good. In the shaft the ledge is 10 ft wide, and the Lucky Rodge, the Kinkaid and the Minnie veins. The shaft has been sunk to a distance of 60 ft on the Lucky Rodge, and a drift has been run 12 or 15 ft north from the bottom. The ledge is narrow, but is rich throughout. Extensive works are to be put up on this claim.

STANDARD COX.—*Standard*, Aug. 4: The west drift, 350 level, is in 200 ft. The ore is good. In the shaft the ledge is 7 to 15 ft wide, of very fine ore. The winze in the west crosscut, 550 level (inclined), is down 47 ft. The upraise on this ledge to connect with the north drift, new shaft, is up 56 ft. The ledge is eight ft wide, of good ore. In the West Standard they are stopping on a ledge 10 ft wide, of very rich ore. They are also stopping in the south drift, 550 level, where the ledge is eight ft wide, of good ore, and in the Glides stop the ledge is three ft wide.

RED CLOUD COX.—The east crosscut, 400 level, was extended 12 ft further during last week, and a ledge was cut, into which has now been cut 12 inches. The ore assays from \$15 to \$30 per ton. A progress of 12 ft was also made in the west crosscut, same level. On the Packard and Morton vein, from the same vein, a drift has been started south, which is now in a few ft, and has run under a shoot of ore of very good quality, assays from which go \$55 per ton.

DUDLEY.—The north drift from these workings is now in 167 ft, and the south drift 110 ft.

NOONDAY AND NORTH NOONDAY.—The north drift on the 200 level has been extended 12 ft during the past week; total length of drift, 32 ft. The south drift has been extended 215 ft; progress during past week, 15 ft. A station has been cut out during the past week on the 212 level, and a crosscut run west from the station 14 ft.

DEFIANCE.—The shaft has attained a depth of 190 ft, and, following the footwall of the ledge, the bottom is in all quartz. Heretofore the quartz has been found more on the hanging wall, and it has been found by crosscutting. It now appears to have widened out to the full extent of the fissure.

SUMMIT.—The north drift, 200 level, has been advanced since last report nine ft; total length, 310 ft. The ledge is 18 inches wide. The east crosscut from this drift is in 194 ft; progress during the week, 18 ft. The rock is somewhat softer than it has been since starting. The north drift, 300 level, is in 204 ft; progress during the week, 13 ft. The ledge is three ft wide, and looks well. The south drift, same level, has been extended during the week 25 ft; total length, 215 ft. The ledge is two and one-half ft wide.

BONIE COX.—The south drift, first level, is now in 136 ft. The south drift, second level, is in 118 ft. The east crosscut, third level, is in 304 ft. The west crosscut, third level, is in 140 ft.

BUTLER COX.—The south drift, 350 level, has been advanced since last report 15 ft; total length 131 ft. The ledge is two ft wide of good ore.

BLACKHAWK.—The winze from the 320 level is down 120 ft on the Warren vein, and the ledge shows an improvement. The drift north on the same vein is in 135 ft, and the ledge is 10 ft wide. The east crosscut, same level, is in 150 ft, the rock being very hard, with occasional seams of clay.

SOUTH BUTLER.—Work in this mine is now confined to the 350 level, where drifts are being run on the ledge and winze No. 2 is being sunk. The latter is now down 30 ft, where the ledge is looking well.

BONNIE COX.—An average progress of about 15 ft per week is being made in sinking the shaft. It is now down 378 ft, the ground being very wet and working easily.

UNIVERSITY.—The new three-compartment shaft is now down 44 ft, timbered the entire distance with 8x8 timbers. A ledge is coming in on the west side the whole length of the shaft.

DOUGLAS STANDARD.—The west crosscut has been run since last report 15 ft, total length, 45 ft. The ground is somewhat harder. The east crosscut is now in 40 ft; progress since last report, 11 ft. The ground is hard blasting porphyry.

RECHER.—The east crosscut, 200 level, is now in 150 ft, and the formation is of a favorable character. The west crosscut, same level, is in 80 ft.

NEVADA.

MOHICAN.—*Transcript*, Aug. 1: The Mohican quartz mine, at the head of Gold flat, has been leased to a company of practical miners. The miners were formerly driven out by the water, but the work done in the Thomas mine has furnished it with thorough drainage. The ledge in sight is large and shows well.

ITEMS.—*Footlight Tidings*, Aug. 2: At the Chavanne shaft of the Rocky Bar mine two companies of tributaries are at work on the 300 level, and the rock is said to be looking very well. A contract has been let for sinking the shaft to a depth of 50 ft below the 300 level, at which point the drain drift through to the New York hill ground will be started. A contract for running 50 ft on this drift has also been let, and the work started on the New York hill ground. Rube Thomas has discontinued hydraulic mining in his claim on the "Slide" for the season, as the V flume requires all of their surplus water to supply the town reservoirs. He will do some work during the summer by drifting in the gravel. The ore now being extracted from the Machine mine looks better than ever before. It is very heavily charged with sulphurates. They have eight Frue concentrators running and save several tons of sulphurates daily. The Shamrock mining company is pushing the erection of the new hoisting works. In the meanwhile the new shaft is being sunk to water level. The Surprise Con. mine, near Allison ranch, contains two lenses embracing 2,500 linear ft—one of 1,000 ft, the other of 1,500 ft—the first supposed to be the old Blinde ledge, the other the extension of the Hartley. The locations have been consolidated, and a company formed and incorporated under the above name. The principal place of business is in Grass Valley, and the stock is owned mostly by four persons, who are practical working miners. The company have sunk a shaft on the Hartley ledge to the level of the clear ledge, and have now reached the main partments, is well timbered, and is intended for a permanent working shaft. At this shaft there has been excellent pumping and hoisting machinery put in place, and enclosed by a good substantial building, 55 by 33 ft in size. The engine is 24-horse power, the boiler tubular, of 40-inch diameter, and 20 ft in length. The pump in the shaft is 12-inch. The ledge in the bottom of the shaft is about 22 inches in thickness, carrying a good footwall and the hanging wall improving. The ledge shows well in free gold and sulphurates, and it is believed that the quartz taken out of shaft will pay for the sinking of the same. Mr. Seth Brown has recently been prospecting in the region north of Truckee, and reports that outlook very flattering. He picked up one piece of gold worth \$15.

PLACER.

ITEMS.—*Herald*, Aug. 2: On the old Shipley lead, about three miles west of Ophir, four practical miners, the Hawkins Bros. and two others, who have been prospecting in that vicinity for some time, have recently made a strike that promises to prove of importance. In a shaft which they have sunk about 30 ft deep, they have a ledge from 18 to 20 inches thick, the ore from which prospects from \$15 to \$20 per ton. They propose to fit up, and crush their rock in the old Shipley quartz mill. The "Rainbow" drift mine, a few miles above the Hidden Treasure, is panning out fully as rich as any mine in the county. They have a breast of over 40 ft, and the gravel pays not less than \$20 per cubic yard. **DUTCH FLAT.**—*Fortune*, July 31: The Polar Star mine has yielded some very rich nuggets within the last three weeks, so says rumor. The last clean-up made by it, after a nine days run, was over \$7,000. It cleans up again today.

SHASTA.

FRANCH GULCH.—*Reading Independent*, July 31: F. W. Wheeler is pounding out \$50 per day with a hand mortar. The Frank ledge is taking out every day a large quantity of rich quartz from the Niagara. The old Scorpion ledge is turning out some ore. There are four men working on the Sparta ledge, near Black Rock, bringing an arastra with fair success. Mr. Heaton says that he and Vandever are getting out some good rock from the old Swasey & Dunlap quartz ledge on Middle creek. They have run their tunnel in about 150 ft. The Extra company, at Copper City, are working on some very rich decomposed quartz from Bully hill. Rich placer diggings are also being worked in the same locality. Mr. Cannon has shorted the No. 20 level at \$2,000 out of a quarter acre of ground. Mr. Potter has his new quartz mine on the ground at Spring creek, and will begin to crush ore immediately.

SIERRA.

WILBOURN COX.—*Messenger*, Aug. 2: Work has again been commenced on the Wilbourn Con. mining company's ground, the location of which is about three miles south of Gold Lake, what is known as Thompson's ridge, on the same range as the rich diggings recently discovered above Sierra City. The company will put down a shaft in this granite to sufficient depth and then run a drift to strike the channel. A shaft was sunk on the ground two years ago, and the finest of gravel was obtained.

TUOLUMNE.

ITEMS.—*Independent*, Aug. 2: About 100 pounds of quartz ore were shown us to-day, taken from the "Spring Gulch mine," which equals anything in the way of mill rock which we have ever seen in this county. This was sprinkled with gold all through, some of which was very coarse. A portion of the ore from which this was taken was about 8 to 8 ft wide. Near the "Spring Gulch mine" is the "Hunter Con." This has recently had the addition of a new 10-stamp mill, and has recently struck a rich body of ore. The "Starr King" has resumed operations, under the superintendence of Mr. Floyd, and a rich strike of ore has been made in it. The "Soulsby," "Confidence" and other mines are turning out steady and good work. A fine ledge is also the ore of another gulch, Big Oak flat, has struck good paying rock at three different places along the ledge, which is quite large, and some of the rock is very rich indeed, being covered all over with specks and threads of beautiful yellow gold. It is usually pounded out with a mortar, and besides there has been saved a considerable quantity of milling ore; some of which shows gold in just every piece, and will pay over \$100 per ton. The gulch, which runs along side of this vein, has been one of the richest in California. Mr. McCortea has just completed a cut and tunnel from near the gulch to the vein, about 70 ft, where he has struck rock that prospects very well; has not yet cut through the vein, which, at this place lays quite flat, with a singular dip to the eastward towards the gulch. There is a single dip to the westward, and a fine vein line. At the point where the tunnel strikes the vein there is a crevice through which a strong current of fresh, cool air comes up from below, with force enough to blow out a candle when held near it. This current of air is quite cold and pure, and by holding the ear close to the crevice, a soft, musical sound can be heard, like the murmuring of distant waterfalls. The ore is also the ore of another mine, on the west side of Big Oak flat, known as the Slate Gulch mine; from several parts of which he has taken good ore while opening the mine, both by shafts and tunnels, and has generally succeeded in making it pay its way. This mine is now bonded to O'Connell and Savory for \$3,000. It was near this mine that McCortea found \$350 in gold dust, on the surface near the trail, all in a bunch, about two years ago.

NEVADA.

WASHOE DISTRICT.
NORTH BONANZA AND FLOWERY.—*Gold Hill News*, Aug. 6: Sinking the main shaft is making fair progress. The north drift, 400 level, is nearing the vein and will cut into it diagonally during the coming week. The Flowery

crosscut, 300 level, is in a very promising formation o quartz, assaying well.

FRANK COX.—Two and a half ft per day are being added to the east drift, 1000 level; total length from the main north drift, 152 ft.

OPHIR.—A joint Mexican crosscut has been started on the 2000 level in search of the west wall and to prospect the ground in that direction. The joint Mexican winze from the 2100 level is making two ft per day, through blasting porphyry carrying some water. The drift north and on this level is averaging four ft per day, through a harder formation of vein porphyry; total length, 52 ft. The incline is now 140 ft on the slope below the 2300 station, and continues in a fine vein formation with streaks of quartz.

CALIFORNIA.—The face of the joint west crosscut, 850 level, is in harder rock than formerly and is encountering some water; total length, 532 ft. On the 1850 level the winze from the north end of the ore stops is down 20 ft in vein material carrying quartz in streaks.

ALTA.—A raise is being made from the 1450 to the 1350 level, in ore, to connect the ore bodies on the two levels, preparatory to stopping out.

MEXICAN.—A crosscut joint with Ophir has been started west on the 2000 level, which is making two ft per day, and will be driven with all speed toward the west wall of the vein.

GOLD & CERRY.—Three ft per day are being added to the length of crosscut No. 3, 1700 level; total length from the main lateral drift north, 1,063 ft, the face in clay and porphyry.

OCIPENTAL.—The lower tunnel has been enlarged and repeated throughout, and from a point 2,434 ft from the shaft a winze has been run on the dip of the ledge 110 ft in perpendicular depth, and from a point 100 ft down a crosscut run west 90 ft through a well-defined vein of low-grade ore.

NEW YORK.—The crosscut on the 1200 level has passed 100 ft through favorable vein matter and is now in the clay and east casing of the vein.

CHAMBERLAIN.—On the 850 level the joint west crosscut is averaging two ft per day through hard rock carrying some water. The raise from the south drift, 1500 level, is up 25 ft and passing through low-grade ore. On the 1650 level, winze No. 2 will be reached some time this week. East crosscut, 2150 level; is in harder rock than formerly, the face 90 ft from the main south drift.

JULIA CON.—The winze from the 1800 level is down 110 ft, and the bottom is in a promising formation of quartz.

OVERMAN.—A drift has been started north on the 1000 level, from the bottom of the winze from the 1600 level, to connect with that south on the 2100 level of the Belcher.

CON. IMPERIAL.—The north drift, 2000 level, is in 555 ft, and passing through quartz and porphyry.

LEVATHIAN.—On the 750 level the south lateral drift is pushing ahead in easy blasting rock with occasional streaks of quartz. The north lateral drift, on the same level, shows less quartz; material in face, hard ledge porphyry.

CALIFORNIA.—The winze from the 1000 level has attained a depth of 258 ft, the bottom in hard rock carrying considerable water.

LADY BRYAN.—The north and south drifts, 600 level, and crosscuts from them are all in promising quartz, but of low-grade quartz.

THOMAS.—The upraise from the east drift, third level, is in low-grade quartz.

WARD.—The shaft has attained a depth of 1,588 ft, and is passing through bird's-eye porphyry, carrying stringers of quartz.

EUREKA DISTRICT.
EUREKA TUNNEL.—*Sentinel*, Aug. 1: The tunnel is now in close on to 750 ft, the last 50 ft improving in ore indications with each blast.

SILVER COXON.—This mine is taking out nothing but ore, and it improves in richness as greater depth is attained. We have been shown some beautiful specimens from the lower workings of this mine—genuine nuggets. Sacks full of very rich ore are now stacked by the mouth of the shaft.

ORANGE.—The shaft from the end of the 500 tunnel is now down about 90 ft. Two shafts, three men each, are employed, and they raise only such ore as is met with in sinking.

PHOENIX.—The Phoenix is in running order, and some ore is being shipped to the Richmond company's furnaces. Several large bins are now well filled with good ore from this mine.

REBEL CREEK DISTRICT.
OMIO LEDGE.—*Silver State*, Aug. 2: This ledge situated near Snapp's station, on the Idaho road, was discovered last week. It has been developed to some extent by a shaft, and is said to be large, rich and well defined. Samples of the ore have assayed from \$300 to \$2,000 in silver per ton; but it is scarcely possible that all the ore is as rich as these samples.

WILLOW CREEK DISTRICT.
ITEMS.—*Paradise Reporter*, Aug. 2: George White, who has been prospecting in Willow Creek district, returned last Thursday with several samples of ore from a ledge he located there. The samples were left with Judge Harlan for assay, and after the test showed an average value of \$301.78 in silver per ton.

ARIZONA.
ITEMS.—*Arizonian*, July 30: We have the best of news from the Tiger mill and mine, in Bradshaw mountain, about 40 miles south of Prescott. A private letter recently received states that \$40,000 in silver bullion, ranging from 1,700 to 2,250 fine, had been shipped. The working shaft is now down about 300 ft. People say the mill is the most perfect ever set up in Arizona. The placer mines of Clifton, Apache county (or more properly the newly-discovered gold region in the southern part of the county), are proving to be immensely rich. Miners are flocking to the new placers, and 23 claims were recorded in one day. Two men are working on a claim from which it is estimated that they are taking out, at the least calculation, \$1,000 per week. In Pinal county the Santa Catalina district improves. Several assays have been running as high as \$2,800 in gold from rock taken out of the Highland Mary ledge, which is in the Santa Catalina mountains, about 65 miles southeast of Florence. Plenty of wood and water all over the district. In Big Bug district, quartz and placer miners are at work. The Tiger mill, on Turkey creek, is running on good ore. The Southern Belle ledge is realizing ore at \$60 per ton, worked by the arastra.

COLORADO.
SUMMIT COUNTY.—*Miner*, July 23: Carbonates have been discovered on Gibson hill, which is between French Gulch and Gold Run. Six or seven shafts have been sunk, and one tunnel is being run. The Superintendent reports that they are taking from the tunnel daily not less than 30 tons of ore. Good mines have been struck between Breckenridge and the range. Sam Conger has sent down 112 sacks of silver ore to Denver. He has a large fine line of rock, 20 to 30 ft. This ore was from a point three miles from Breckenridge southwest from the road. F. J. Elbert has struck good ore opposite Conger, between Indiana and Illinois gulches. Wannemacher has got good ore between Conger and Pennsylvania gulch.

PERU DISTRICT.—Cyphers & Mendonhall have struck a ledge from which they are taking ore that assays from 1,700 to 2,250 fine. They have stripped it over 100 ft in length and exposed from 8 to 13 inches of mineral. Other strikes are being made on Cooper and Ruby mountains. Old prospect holes are being sunk down and are showing good ore. The old black quartz in these ledges is running from 75 and 80 to 100 ounces. The new town will probably be near Commodore Deane's old cabin. The mines are large fissure veins, low grade on the surface, which improve rapidly as depth is gained. As it is only 14 miles from Georgetown it is easily accessible.

TEX MINE.—On the Sheep mountain, in the Kearsarge, 7 ft of mineral have been exposed on the face, and at depth of 5 ft there are no indications of bottom.

GUNNISON & SAN JUAN.—A gold lode was discovered during the coming week. The Flowery

Table of Highest and Lowest Sales in S. F. Stock Exchange.

The Mining Share Market.

Without what may be termed a "booming" market, the past has been a satisfactory week to dealers in mining shares. After a season of depression, with sales slow and limited in extent, the market gained animation and strength at the very end of the week. Monday came and with it an incisive, sudden and unexpected upheaval, the north end stocks being especially buoyant. Chippers in hastened to realize, this being the first opportunity that had offered for a long time to make a profit, while short sellers, alarmed at the prospect, lost no time in filling outstanding obligations, a combination of movements that served to keep life in the market for several days after. Indeed the week closes with great activity and a cheery outlook. On Wednesday there was a lively call at advanced figures for Comstock shares, the demand reaching to nearly every standard stock from Utah to Silver Hill. As there have been but few Eastern orders since the June collapse, these purchases must have been mostly on home account, disclosing a growing confidence among local operators in this class of securities. But how to interpret these movements it would be difficult to say. The stock manipulator, like the oarsman, looks one way when he pulls the other. Stocks may be put up on their merits, through improvements occurring in mines or through the efforts of insiders who, having discovered the worthlessness of the mines, may be desirous of getting out. The Comstock sphynx sits in the Washoe deserts, mysterious and dumb, a puzzle to all save the keepers of the oracles themselves. Outside worshippers are at a loss to know whether it is coming or vanishing—a stern reality or only a myth. There is evidently a growing belief that important developments are about to transpire at more than one point along the great ore channel. What serves to strengthen this impression is the close personal attention that Mackay and Fair are just now giving to operations there. These men are not apt to devote themselves individually to this sort of work, unless some important revelations are expected and even imminent. At any rate, this is the construction put upon their constant presence in the lower levels of certain mines of late. Then, too, the knowing ones are generally beginning to stand in to the support of the old favorites, which also seems significant of the early approach of the good time coming. We trust it will not this time prove a failure, nor be much longer delayed. At the very end of the week the Comstocks, with one or two exceptions, closed stiff, while Bodie and other outside stocks were a little off. This class of mines are, however, generally looking well, and with the opening of new ore bodies, their shares would quickly respond in higher prices.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ITEMS.—*Dispatch*, Aug. 2: The Gray Eagle mine is being thoroughly prospected. Five straps of the Empire mill are being run on rock taken from the mine as a test. The Victoria mine, south of the Empire, is also being prospected by San Francisco capitalists.

DOWNS.—*Ledger*, Aug. 2: The new double-compartment shaft is down 200 ft, and connection made with the old shaft. Ventilation is now good. In the Lincoln, running drifts by contract system is the work in hand. The mill is running. The Potosi, between Amador City and Plymouth, is inactive, with the exception of keeping down the water. The Maryland continues to work a small force of men.

BUTTE.

BANNER MINE.—*Merrill*, Aug. 1: C. W. Keeney, Superintendent of the Banner mine, went to San Francisco Wednesday, taking with him 32 pounds of quartz gathered from the old tunnel run by McSmith and Sparks in '59. Old prospectors and miners who saw the rock, estimate its value at \$130 a ton on the dump.

CALAVERAS.

CONGO QUARTZ MINE.—*Chronicle*, Aug. 2: This mine is situated in Negro gulch, near Leavitt's ranch. The main shaft has reached a depth of 100 ft. The ledge, which showed very wide on the surface and was somewhat broken up, has narrowed down to a solid, well-defined vein four ft thick, all carrying gold. Good judges estimate that the ore will average \$30 per ton, taking the entire ledge as it is.

CHAMBERS.—An immense over-shot wheel is to be built to run the hoisting gear, and the erection of a 20-stamp battery is to be commenced immediately. The Champion is looking better than at any other period in its history, and the mine has now been thoroughly prospected to the depth of 500 ft.

EL DORADO.

ITEM.—*Democrat*, Aug. 2: Last Thursday the St. Lawrence mill and mining company closed a sale of their fine 30-stamp quartz mill and hoisting works to the Placerville gold quartz (the old "Pacific") mining company. This is the finest and most complete quartz mill property ever put up in this county. It will be at once removed to the mining ground of the purchasers, on Pacific hill, just south of this city.

MONO.

TIOGA DISTRICT.—*News*, Aug. 2: Tioga district is situated about four miles north from Mount Dana, and adjoins the south line of the Bodie mining district, and in a direct line is 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a ledge 15 ft in width, which assays well; the Ahwaga, with a shaft sunk some 25 ft, following down on the ledge from the surface, looking well; the Bevan, on which work has been done by means of a shaft now 18 ft in depth, showing a ledge extending the entire width of the shaft, about 10 ft; the Tipson, in 25 miles distant. There are now some 40 mines taken up, principal among which are the Atherton, opened by a cut now in about 20 ft, uncovering a

Deep Mining on the Comstock.

We publish this week the address of Prof. John A. Church, on "Deep Mining on the Comstock," delivered before the Bullion Club Thursday night, June 19th. In preparing for the Government his report upon these mines, he had good opportunities to study the questions which he discussed; and from the careful manner in which he does all of his work, his views will be eagerly read by many of our readers:

For many years, engineers have discussed with much interest the subject of deep mining, the point in question being the greatest probable depth to which the earth's crust could be penetrated. Opinion settled with considerable uniformity upon 4,000 feet as the limit to which the existing conditions of labor and machinery would allow mining to be carried with profit. No mine has reached that depth, and the question was really no more than a theoretical one until the appointment of the famous British Commission for inquiring into the probable future of the coal supply. In that investigation, the depth to which the earth's strata might be robbed of their coal was necessarily an important item.

But it appears to be reserved for America to put this important question to the first practical test, and under circumstances which are undoubtedly the most notable and interesting in our mining annals.

The past 20 years have witnessed the discovery in our country and the growth of the most important mines of silver and gold known in the history of the world, with one exception. Potosi, in South America, is said to have produced \$600,000,000 from its mines, while the Comstock lode in Nevada has yielded but little more than half that sum. But at Potosi there were more than 30 principal veins, while in the Comstock region all but 2½% or 3% of the product has been collected from a series of 15 or 16 large masses of ore lying in close juxtaposition to an eruptive dike about four miles long, and forming one homogeneous lode. This wonderful series of deposits has supplied no less than 2½% of all the gold and silver that have been extracted from the whole earth since the voyages of Columbus; and if any other lode has a record that can be compared with this, I have not been able to find it.

It is difficult to arrive at the true product of the Comstock mines; for they were opened at a time when statistical matters were but little valued in the West. At that time, when the bullion was obtained, little attention was paid to accounting for it to the world. Now a different state of things exists, and careful records of mining and milling operations are kept; but the early period unfortunately covers just that part of the lode's history in which the rich top-rock that occurs in most veins was worked, and the confusion then introduced can never be removed from the statistics of its yield.

After going over the numerous and somewhat contradictory authorities as carefully as possible, I have summed up the entire product of the lode from 1858, the year of its discovery, to the end of 1878 at \$291,171,605. This represents only that portion of the yield which was accounted for to the stockholders; and to ascertain the true yield of bullion, some addition must be made for the product from tailings and battery slimes, both of which, by Western custom, are perquisites of the mills. It is obviously difficult to learn the true yield, or estimate fairly for these items; but if they are supposed to yield \$5 per ton of ore, and the quantity of ore is 6,500,000 tons, they will represent a product of \$32,500,000. This brings the whole yield of the mines to \$323,671,605. Finally we may add \$40,000,000 to this sum for the losses in working, and the account with the mines will stand about as follows:

Duration of mining.....	20 years
Number of bonanzas.....	16
Tons of ore extracted.....	6,500,000
Value of ore per ton, nearly.....	\$56.00
Yield in mills.....	44.30
Yield from tailings and slimes, per ton.....	5.00
Lost in tailings, per ton.....	6.00
Total value of ore.....	\$363,671,605.00
Value of ore per ton.....	291,171,605.00
Yield from tailings and slimes.....	32,500,000.00
Lost in tailings.....	40,000,000.00

In every aspect from which these mines are viewed, they are remarkable. They have been the most productive of bullion; they are the hottest excavations which have been made in the earth's crust; they are the deepest opening on the American continent, and are rapidly becoming the deepest in the world; and finally, their fortunes fluctuate between the absolute extreme of dividend and assessment, of rich bonanza and barren horrasca, with a rapidity that has no parallel in vein mining. Such an array of superlatives in description may be thought to defeat itself, but every one of them is strictly true when applied to these mines. The last of these items covers the most important characteristic of the lode, and its accuracy is well exhibited by the recent history of the mines.

In 1873, two mines in Gold Hill—the Belcher and Crown Point—were in bonanza, and continued in active production for three years longer. In that year, another discovery was made, nearly a mile north of these mines; but with this exception, the whole lode has been absolutely barren of new discoveries from 1873 to 1878, though work was vigorously prosecuted

along its whole length of four miles. This work has covered a depth of probably 700 or 800 feet, and in some portions much more than this; but, with the exception spoken of, no discovery was made in the period of five years. Yet, with all this hard fortune, the Comstock never produced so much bullion, never paid such large dividends, and never showed such a profit over expenses as during this very period.

The reason of this is, that the single discovery mentioned developed into a series of ore bodies that, by the end of 1878, had yielded no less than 37% of the whole Comstock product. The ore was richer, the percentage extracted higher, and the profits greater than ever before known.

Such facts illustrate the peculiar characteristics of this great lode, and I have brought them to your notice because the chances of deep mining in that region are largely governed by this peculiarity. The ore bodies, whose great wealth made 1,200 feet of ground more productive than the whole lode had ever been before in an equal space of time, are now so far exhausted that their immense profits have ceased, though they continue to supply large quantities of poorer ore. New discoveries have been made in their neighborhood, and ore is now extracted from them, but their magnitude and value are unknown to the public. So far as trustworthy public information goes, the whole Comstock lode is to-day a ground for assessments, but not for dividends of importance.

It is under these circumstances that the manager of the mines have prepared for exploring the lode at depths which approach the limits that have long been considered practicable for working in the earth's crust; and it is under these circumstances that I am to speak to you of the chances which this deep mining will have. I will begin with the announcement that I consider those chances just as good as they ever were at shallower depths, and go on to offer to you my reasons.

I have told you that the Comstock lode consists of a number of independent ore bodies disposed upon an eruptive dike. The dike runs north and south and dips toward the east, and the ore bodies imitate it in both respects. The earliest workings were upon the outcroppings of quartz; and as successive depths have been reached, a series of hoisting shafts has been sunk, each one being placed eastward of its predecessor. Four lines of these have been established—one at the outcrop, one reaching to a depth of 500 or 600 feet, and one attaining a depth of 1,000 or 1,200 feet. This is the line which has been in use for the last 10 years. Finally, in the fourth line are placed those deep shafts of which none has reached the lode, and the future prospects of which form the subject of my remarks.

These are six in number: The Union shaft, 1,500 feet east of the present line; the C and C shaft, so called because it is the joint property of the California and Consolidated Virginia mines; the Requa shaft, sunk by the Savage, Hale & Norcross, and Chollar-Potosi companies, and named from the Superintendent of the last-mentioned mine; the Taylor shaft, sunk by the Yellow Jacket, Kentuck, Crown Point, and Belcher companies; the Forman shaft, sunk by the Overman and Caledonia companies; and the Oshiston shaft, sunk by the Gould & Curry and Best & Belcher companies. These are advanced from 2,500 to 4,400 feet east of the present line, and they are expected to reach the lode at depths varying from 2,500 to 3,500 feet. From the junction, inclines will be sunk on the dip of the lode, which may carry the workings 1,000 feet farther in depth. The northern or Virginia end of the lode will have four and the southern or Gold Hill end will have two deep shafts.

In every respect, the appointments of these shafts are suited to the great work expected of them. The hoisting and pumping machinery is of the most powerful construction, and the work of sinking is prosecuted with great vigor. Their position is such that the North Consolidated Virginia shaft, together with the Oshiston, Requa, and Taylor shafts, forms one line, 2,500 feet east of the present line of works, and covering 12,000 or 14,000 feet of the lode in which it found its most productive portion.

Turning now to the immediate object of our inquiry, it is not to be denied that the long-continued barrenness of 18,000 feet of ground that was once productive has awakened serious doubts of the permanent character of Comstock mining; and while engaged in a careful examination of all the mines, I made the question of future probabilities one of my principal subjects of inquiry. I found that no ore body on this lode has been discovered from the workings in another ore body. In the Chollar-Potosi, several important bonanzas were included in a great mass of quartz, and one or more of them were discovered in the manner which I have described. The same is true of the California and the smaller Consolidated Virginia ore body; but I have learned to look upon such groups of ore bodies as mere parts of one great bonanza, and the assertion I have made is true when applied to the case of bonanzas which are strictly independent. They are not connected by stringers of ore, nor do they overlap in any way that makes it possible to feel for one from the known position of another. Entirely disconnected, they are surrounded on every side by barren ground, and this often reaches upward and downward and on both sides for hundreds of feet.

In an ordinary fissure vein, where a rich part of the ground is worked out, there often remains a steady supply of poorer ore from the main filling of the vein. But this is not the case on the Comstock. When the true bonanza is ex-

hausted, large quantities of poor ore are often scraped up from the corners and sides of the great mass; but in time this also fails, and the miner finds his excavation surrounded by country rock on all sides in a fashion that veins do not exhibit. The quartz once removed, nothing like a vein remains, and the ground beneath him resembles perfectly the rock that stretches for miles on either side.

In a lode of this kind, barrenness for 500 feet no more proves the exhaustion of the lode than barrenness for 100 feet of depth. These bodies of ore lie in a thick mass of layers composed of eruptive rock. At a certain period, an immense quantity of another eruptive rock was poured out upon them as they stood in their inclined position. It loaded them with such a weight that they began to elide upon each other, the upper layers sliding upon the lower, and the movement must have been accompanied by crushing and breaking of the layers on an extensive scale.

Into these crushed portions and into the opened seams of the rocks poured a stream of water, bringing with it quartz, gold and silver; and these were not only deposited in the crevices, but the solid rock was itself dissolved, and metalliferous quartz was left in its place by the process known to geologists as substitution.

Ore bodies formed in this way may be in the near neighborhood of each other, but they may also be far removed and have no other relation than that they occupy the same line of crushing and movement. Mining on the Comstock has gradually adjusted itself to this condition of things, and it is rare to find an effort made to follow up what in other mines would be considered good indications of metal. If an ore-bearing seam is found, its character is carefully ascertained, however insignificant it may be; for the bonanzas always begin in a small way, whatever proportions they may reach afterward. But in general exploration, the system pursued is to cut through the rock layers at points sufficiently near to make sure that no important ore body can escape early discovery. Irregular as the Comstock ground is, the work upon it is more uniform than is common in metal mines.

I have brought these points before you to show that the present state of things is nothing new on the lode. At all other times, some of the mines have been in barren ground, and the only thing remarkable in the existing condition is the vertical and linear extent of this barren ground. It covers nearly the whole length of the lode for perhaps 600 feet of depth as a minimum. This is unpleasant and not profitable; but I cannot acknowledge that it is proof of exhaustion.

From the facts given, you will see that the question is really brought down to one point. The ore bodies exist because certain parts of the ground were opened and crushed by a weight laid on the surface. The almost uniform cessation of ore at a given depth might well give rise to the suspicion that the force mentioned was exhausted in the work it did upon the rock at higher levels. The geological aspect of the question may, therefore, be expressed by the question: "Was the weight to which the lode owes its formation sufficiently heavy to extend its effects to depths greater than 2,500 feet, which we may assume to be the greatest present depth of the mines?"

I think no observer, who will go upon the ground and search out the boundaries of the vast mass of rock that compose this weight, will imagine that its effects can be confined to the shallow depth named. Indeed, a visit to the ground is not necessary. The condition of the ore in the great bonanzas gives strong evidence against the supposition. All the ore taken from the lode, with exception of scattered hunches, the outliers of the bonanzas, and with exception also of that now mined in the Ophir, Union and Sierra Nevada, has been found above the 1650 level. A hundred feet above that point, the effects of the weight were so tremendous that an ore body 200 feet thick was formed in the mass of rock which its action shattered. It is evidently impossible to suppose that such results were obtained by the operation of a force that was fast reaching the end of its powers. It would be singular if the greatest effects were exhibited in the decline of the forces that produced the ore bodies; and the idea that the Comstock is exhausted must be rejected on the mere statement of the conditions which the latest bonanzas exhibited.

During the past 18 months, repeated accounts of the discovery of ore in three mines—the Ophir, Union Consolidated and Sierra Nevada—have been made public, and the mills are now crushing ore from one or two of these mines. I believe these discoveries were made about 600 feet below the 1650 level, and it is possible that the continuance of the Comstock as a producer of ore in depth may be decided already in the affirmative. But leaving out of consideration these discoveries, of which I have no definite knowledge, and confining our attention to those facts which were known and capable of scientific examination in 1877, it must be acknowledged that below the 1600 level all the mines but one, or possibly two, were barren for a depth of 600 feet, and most of them for as much as 800 and 900 feet, and even more. If the sources of the ore and the forces which placed it in position were existing in undiminished vigor, as it is my purpose to impress upon you, there must be some other antagonistic cause in operation which has prevented the formation of ore bodies at this particular depth and produced a barren zone.

Such a change of conditions is discernible, and though a complete retrospect of the mode in

which the great lode was formed would occupy too much time, I can point out to you one of the most striking facts which the study of the lode has brought out.

Through the whole Virginia section, and also in a large portion of the Gold Hill ground, the ore-bearing portion of the lode has had a very steep pitch. Angles of 45°, 50° and 60° were common. The great bonanzas may be said to stand vertically; for, while they dip throughout their whole height, this dip is both east and west on alternate levels, and the result is not far from perpendicularity. The characteristic of the productive ground then is steep dip.

Barren ground is marked by just the opposite peculiarity, and wherever the dip has flattened, whether near the surface or at a great depth, the flattening of the lode has been followed by cessation of ore. Very marked instances of this are shown in the Yellow Jacket, Gould & Curry, and other mines. This is precisely the state of things now found in the existing great barren zone, and to this flattening I trace the disappearance of ore. There is no reason to suppose the change a permanent one, or to deny the probability of ore making a gain in depth just as it has repeatedly made at higher levels when flat dip has been followed by a steeper inclination.

It is on account of this flattening that the new shafts have been placed so far to the east. Whether the distance selected, about one-half mile, has been sufficient, must be proved by the results; but the conclusion to which the history of the lode necessarily leads us is, that, if they find the lode increasing in dip at the point of their intersection with it, the prospects for a line of bonanzas on a new front removed half a mile from the old one will be just as good as if it were one or two thousand feet nearer the surface. The added depth is not likely to decrease the results.

But the theoretical probabilities of finding ore are not the only elements in the problem of constructing these deep shafts. New conditions have come in—new not only on the Comstock but novel in the world. In the first 1,000 feet of depth, the mines were often close and hot, and the ventilation poor. Since that was worked out, the ventilation has been so improved that the works would be quite comfortable if the rock had remained as cool as it was above. But it has become hot, and is steadily growing hotter. The men work in an atmosphere of 108° to 112° in a great many drifts. The rock at the 2000 level is 130° Fahr., and, ominous of future event, water of 156° Fahr. has entered at least one of the mines.

At the same time, the quantity of water in the rocks has increased. A well 2,500 feet deep will drain a large territory; and when, from the bottom of that well, a gallery is run two miles each way, north and south, and at numerous points in its course, other galleries are cut through the rocks, quadrupling the length of the main drift, the whole network forms a drainage system vast in extent and of the most perfect arrangement.

Already the mines are raising not less than 4,500,000 or 5,000,000 tons of water a year, and the upcast shafts through which the air-current leaves the mines send out a whirling column of vapor 40 feet high. Will the water increase so as to make mining unprofitable, or the heat increase so as to make labor impossible in these deep shafts?

The popular fancy is more impressed by the striking effects of the heat, but the water problem is probably the more serious of the two. An excellent system of ventilation, closely adapted to the conditions of work in heated air has been devised, and is capable of further expansion. The heat will probably increase, but its effects can be guarded against sufficiently to make work in the next thousand feet of depth more comfortable than it has been in the last thousand. Much as our sympathies may go out to men who have to work in these hot galleries, their efficiency as miners proves conclusively that the conditions of their work are not startlingly oppressive. With all their disadvantages, they accomplish as much in a day's work as the best average miners. This efficiency will not be lightly lost. Every few months witness improvements in ventilation, and it is probable that the arrangements at the new shafts will more than compensate for the greater heat which they must expect to encounter.

When we study the subject of drainage, we at once find ourselves in the presence of much more serious conditions. The vast ramifications of the mines, extending more than 200 miles in aggregate length, and increasing probably 12 miles each year, form a drainage system that must collect the local rainfall very thoroughly. Fortunately, the quantity of this is not great; but the rocks also contain immense stores of water, from which the pumps are constantly drawing as the deepening of the mine taps one reservoir after another. Whether the annual supply of 5,000,000 tons is drawn entirely from these two sources, or is maintained partly from water channels that tap distant and exhaustless stores, can not be determined now.

Virginia stands about 1,500 feet above Carson plain, and the mines are already nearly 1,000 feet deeper than Carson river, four miles away. It is not at all improbable that the drainage of large areas which would discharge into this and other channels may be diverted to the mines. The drainage of the mines is already more difficult and expensive than their ventilation, and its difficulties are likely to increase more rapidly with depth. The completion of the Sutor tunnel will give the mines a new lease of life, and improvements which are always possible in

mechanical appliances will further lessen the cost and labor of drainage.

When the present working shafts were decided upon, they were thought to be very formidable undertakings, and it was supposed they would suffice for the work of the lode for many years. But the vigor with which the ground has been worked has reduced their life to ten years. They represented an advance of about 600 feet in depth in the vertical shaft. The new line represents an advance of, at least, twice this increase in depth. No one can pretend to anticipate their history; but it has been my effort to show you that their prospects are good, though they are begun after a continuance of disappointment quite unprecedented on the Comstock and an expenditure of assessments entirely unexampled in the history of mining. Their fortunes depend on three factors: the finding of ore, the control of drainage, and the possibility of work in the increasing heat of the rock. I think that a careful examination of the lode and of the mining upon it would discern encouragement in all these respects. The lode in depth bids fair to be precisely what it was nearer the surface, and the unknown quantity is really the exact depth at which the great barren zone will end.

Miners' Law.

The customary law of miners, as stated in the opinions published in our last issue, is not applicable in California to controversies arising between them, or ditch owners, and occupants of the public lands for agricultural or grazing purposes. It has been the general policy of the State "to permit settlers in all capacities to occupy the public lands, and by such occupation to acquire the right of undisputed enjoyment against all the world but the true owner."—*Tarter vs. Spring Creek Co.*, 5 Cal., 398.) But at an early day an exception was made to this policy in cases where the interests of agriculturists and of miners conflicted. By an act passed April 20th, 1852, a right of action was given to any one settled upon the public lands for the purpose of cultivating or grazing against parties interfering with his premises, or injuring his lands where the same were designated by distinct boundaries, and did not exceed one hundred and sixty acres in extent, with a proviso, however, that if the lands contained mines of precious metals, the claim of the occupant should not preclude any person desiring to do so from working the mines "as fully and unreservedly as they might or could do had no possession or claim been made for grazing or agricultural purposes."—*Statutes of 1852*, p. 158.)

Under this act the Supreme Court of the State held that miners, for the purpose simply of mining, could enter upon the land thus occupied, but that the act legalized what would otherwise have been a trespass, and could not be extended by implication to a class of cases not specially provided for. Accordingly, ditches constructed over lands thus held, without the consent of the occupant, though designed to convey water to mining localities for the purpose of mining, were held to be nuisances, and upon the complaint of the occupant were ordered to be abated.—(*Stoakes vs. Barrett*, 5 Cal., 37; *McClinton vs. Bryden*, *Ibid.*, 97; *Fitzgerald vs. Urton*, *Ibid.*, 308; *Burge vs. Underwood*, 6 Id., 46; *Wermer vs. Lowery*, 11 Id., 104.)

Since these decisions there has been some legislation in the State, permitting water to be conveyed, upon certain conditions, across the lands of others. Such legislation, if limited to merely regulating the terms upon which possessory rights subsequently acquired on the public lands in the State may be enjoyed in the absence of title from the United States, may not be open to objection.

GOLD IN SOUTH AMERICA.—In French Guiana gold diggings commenced in 1856, and in the next six years about 13,120 ounces of gold were procured. A few years later the Dutch settlers began to work the gold-fields in their colony, and in the next two years ending 1867 gold to the value of £25,000 (\$125,000) was exported to Amsterdam. In the meantime still greater progress has been made in Venezuelan territory adjoining. In 1869 about 20,000 ounces of gold were obtained there, and the introduction of improved machinery during the last ten years has largely increased the output. Large numbers of Cornish miners, of miners from California and British Columbia, and laborers from the different West India islands have been attracted to these fields; and now it is reported from Surinam and Cayenne that rich veins of gold have been found simultaneously in several parts of the auriferous area which had fair to eclipse the wealth of both California and Australia. One man, it is stated, in four weeks gathered upwards of 40 pounds weight of gold, with little labor, and similar instances of the abundance of the metal are numerous. A regular rush has been made towards the diggings, and it is feared that complications may ensue, if precautions are not promptly taken, in consequence of the conflicting claims of English, Dutch and French settlers, of citizens of the Venezuelan Republic, and of the native tribes. Although gold has not been actually worked in British Guiana, its existence in the interior has long been suspected, and even ascertained; and the fresh discovery must have important influence on the future of the colony. Unfortunately the limits of the British colony and the Venezuelan Republic have never been accurately defined, constant disputes occurring in consequence.

USEFUL INFORMATION.

Embellishing Metallic Plates.

The decoration of sheet-iron or of tin orterne plates by printing with colors, by lithography, and by stamping is considered to be defective whichever is used, so that in the opinion of Messrs. Trottier & Co., of Hennebont, France, a blank remained to be filled up in order to supply the numerous manufactures employing sheet-iron and tin with a product which, while presenting essentially a decoration suitable for the article for which it is intended, offers great resistance to the tools with which it is to be made, and will bear the usage to which it will be subjected. Such is the object sought and which is believed to be fully attained with the novel products forming the subjects of this invention. These products, which it is proposed to term "litho-plastic iron and tin," may in fact be applied to all purposes of manufacture. The plates of iron or other metal having been polished and grained, are submitted to lithographic printing with inks non-eaponifiable by acids, amongst others those having a base of wax, linseed oil and asphaltum, or linseed oils vulcanized by the action of azotic acid, or made so that they cannot be attacked by acids by means of an addition of Jews pitch, and two or more solutions of concentrated india-rubber.

The object of impression being obtained, the parts not covered by the fatty inks are bitten in or deepened by chlorhydric, sulphuric, nitric, or nitrous acids, pure or diluted, or by any other body capable of forming with the iron a soluble combination, or by the aid of an electric current in bathe suitable for this work. The duration of the action necessarily varies with the relief which it is desired to obtain and the nature of the solvents used. The fatty inks which have formed the reserves are then removed either by heating the plates or by solvents of the fatty matters. In this state the iron is submitted either to ordinary tinning or to galvanizing, or to any kind of galvanic deposit, according to the use for which it is intended. The electro-chemical deposits may be applied as reserves, this application being based upon the property possessed by certain metals of not being attackable by acid, whereas the same acids act upon iron. The same lithographic composition will then give an object or impression the reverse of that obtained by the previously described process.—*Mining Journal Sup.*

DYEING.—A new process, by which novel effects may be produced upon textile materials, has been introduced by MM. Gillett & Son, Lyons. The thread or textile fabrics are first dyed black by any known process, and are then treated with gelatine or albumen, and allowed to dry. After this, the materials are placed in a bath (more or less dense) of color obtained by the distillation of coal, and vaporization is then affected either in a wet or dry condition, according to the effect which it is desired to produce; after these operations the materials are washed. The threads or fabrics thus dyed are then ready to be submitted to the operations of drawing, lustering, calendaring, pegging, and other manipulations intended to increase their brilliancy. The treatment of the threads or fabrics with gelatine or albumen may be dispensed with, but without them the coloring matters will not be so well fixed, although they may be brighter. Good results and different effects may be obtained by placing the materials to be treated alternately in baths of logwood and of acetate of copper. The same colors obtained by the distillation of coal may also be employed, not only for materials which have first been dyed black, but for those which have been first dyed with colors more or less dark. For instance, a fine effect may be obtained by the application of aniline violet on French blue; or quite a different effect may be produced by the application of such colors on chestnut or other shades of brown.

STOP-COCK OF EASY CONSTRUCTION.—Take two glass tubes, one of which slides easily into the other, close the end of the smaller tube in the flame of a Bunsen's burner, and make an opening about an inch from the closed end by filing crosswise with a rat-tail file. Connect the two tubes by a piece of rubber tubing, which should fit the smaller tube closely, and the stop-cock is complete. When the smaller tube is pushed into the larger one the cock is open; when shoved back into the rubber tube the opening in the small tube is covered by the rubber wall, and the passage of liquids or gases prevented.—*Edward Hart.*

RESTORING STEEL.—A German magazine gives a simple method of restoring burned steel to a workable condition. This consists in immersing it in a preparation made by melting three parts of pure rosin in a crucible, and after it has become perfectly fluid, adding, with continued stirring, two parts of boiled linseed oil—care being taken to prevent the mixture taking fire, of which there is danger should the temperature be too high.

The electrical resistance of pure water, according to the experiments of Messrs. Exner and Goldechmidt, decreases uniformly as the temperature rises. At 99° C. (= 210.2° Fahr.) it is only one-third of what it is at 20° C. (= 68° Fahr.) A similar result is observed with water acidulated with sulphuric acid.

PREPARING METAL SHEETS AND WIRE FOR COATING.—A special improved process of treating metal previously to its being coated with tin, lead or zinc, has been invented by Mr. Conway, of Pontnewydd, near Newport, England. The present method is to subject the iron, steel, or other metal, to a bath of sulphuric acid, but Mr. Conway's invention does away with the use of acid, and substitutes carbon or hydrocarbon, either in the form of vegetable or mineral tar or hydrocarbons, which may be applied mechanically or by manual labor, but he finds it advantageous to employ a machine by which plates by means of rollers are passed through a bath containing the carbon to be used, thus doing away with what is technically known as "black pickling" in the manufacture of tin and tinned plates. After passing through the bath the plates or metal of other forms go through the usual process of annealing, cold rolling, white pickling and tinning, as is well understood.

A CONVENIENT mode of testing dynamite, sufficiently exact for practical purposes, is the following, recommended by the *Chemiker Zeitung*: Dynamite, as our readers are aware, is simply an infusorial earth, which is saturated with nitro-glycerine, and the explosive energy of a sample will depend upon the quantity of nitro-glycerine it carries. For this purpose, a weighed portion is taken and treated with ether, which dissolves out the nitro-glycerine, leaving the inert infusorial earth unaffected. The difference in the two weighings will give the percentage of the explosive present.

SULPHATE OF BARYTA.—The mineral was scarcely known or used in Europe 50 years ago, but the Chinese have used it in the manufacture of the finest description of porcelain, and also for agricultural purposes, for thousands of years, and it appears its application in the growth of certain crops is marvelous. Capt. Thomas, of Cappagh, Ballydehob, we are informed, after a long and patient investigation of the subject, has discovered a fertilizing manure of astonishing power, the principal ingredient in which consists of a preparation of the sulphate or baryta.

FLAX VS. SILK.—Considerable excitement has been caused in Lyons, France, by a discovery which purports to give to flax all the qualities and appearance of silk. It has long been known that silk is soluble, not only in powerful acids, but also in soda and chloride of zinc; and it is said that these qualities are made use of in the new process. A company is being formed, with a capital of \$6,000,000, for the manufacture of the new textile.—*Iron Age.*

GOOD HEALTH.

The Treatment of Neuralgia.

Aconite is an old remedy in neuralgia, which has, however, not altogether realized expectations which were formed of its value. The power which it often lacks has been lately claimed for its alkaloid by Prof. Gubler, who announced that aconitia is almost infallible in trigeminal neuralgia. This substance was long banished from materia medica for internal use, but it has been employed occasionally since the discovery of a crystallized form by Grehn and Duquesnel in 1871. Its value in neuralgia has lately been investigated by the New York Committee on Neurotics, of which Dr. E. C. Seguin is the chairman. The dose of all forms of aconitia is about the same, the initial dose being about half a milligramme (1-130 grain) twice or thrice a day. Gubler states that the dose of amorphous aconitia may be gradually raised to half a centigramme, but Duquesnel's preparation has to be given with greater caution. There are, however, differences in susceptibility, and some persons cannot bear a larger dose than 1-200 of a grain; while one case was met with in which 1-84 of a grain every three hours was tolerated.

From a trial of the treatment in a series of cases, the committee conclude that, on the average, distinct physiological and therapeutic effects may be obtained by giving 1-100 of a grain three times a day. Of six cases of severe trigeminal neuralgia, one, probably a reflex neuralgia from a decayed tooth, was not at all benefited. Three cases of epileptiform neuralgia were slightly or only temporarily relieved. Two cases were cured. One of these had existed for seven years, with an interruption of seven months, procured by resection of the affected nerve. The results thus afford a partial support to M. Gubler's assertion.

The value of ammoniacal sulphate of copper in the treatment of the same affection has been asserted by M. Fereol in a recent communication to the Academie de Medecine. He states that in cases in which every treatment has failed, even the administration of gelseminum and aconitia, a cure or remarkable relief may be obtained to the most severe symptoms by this drug. Among the examples he gave of its use was the following: Trifacial neuralgia of two months' duration, with absolute (?) insomnia, was unrelieved by the extraction of teeth, quinine, bromide, aconitia, or tincture of gelseminum, hypodermic injections of morphia, or arsenic. From the first day of the administration of the ammonia sulphate of copper there was a notable remission in the symptoms and cessation of the insomnia. In one case the dose was pushed to eight grains without any other accident than nausea. It has the drawback of oc-

causing a persistent metallic taste in the mouth. Only one case of intolerance was met with; in that a grain and a half of sulphate of copper occasioned violent vomiting.—*Lancet.*

Recreation.

"All work and no play
Makes Jack a dull boy."

Poor poetry, but right good sense. As a people we need more recreation. We are desperate workers. Many of us are wasting our vital forces at a fearful rate, without taking sufficient measures to re-create them; a balance in hand subject to such drafts will soon be overdrawn. We must keep it good with fresh deposits or we shall soon have an awkward account on our hands to settle. Enough to eat but no appetite, nervous headaches, sleepless nights, heavy doctors' bills, expensive visits to "the springs," doleful company, regaling their friends at breakfast, lunch, dinner and "between times" with their doleful symptoms, will all be in the bill to foot. Better learn to be happy, instead of miserable, at less cost. But a noted English physician has just been telling the world, through the *Gentleman's Magazine*, that we must learn to turn work into play and play into work. It is drudgery that wears. We need to take pride and delight in our work, get up a little enthusiasm that turns it into a good game of skill. The workman shoveling rock on the macadam, or mixing the bed of mortar, ought to be able to say when he is done, "That's a first-rate job; heat it who can?" Then no less than the painter or the poet he feels the stimulus of an ideal. Every stroke is a pleasure and as he looks back on his finished task honest pride and a good conscience are like lingering music in the soul. On the other hand nothing is more dreary than the effort to be amused. A more pitiable sight rarely pains the eye than the "gentleman of leisure" who has plenty of money and nothing to do but play. He bange heavily on himself. Killing time kills the killer. To live well we need to learn to work sportively and play in earnest.—*Work and Play.*

NEW DISEASES.—Prof. Winckel, the director of the Royal Lying-in Institution at Dresden, has reported to the Congress of Children's Doctors, lately held in Berlin, observations upon a mysterious children's disease, which he had an opportunity of clinically studying in his own institution. An epidemic broke out toward the end of March. Of 23 children attacked, 19, or 82% died, and the average duration of illness in the fatal cases was 32 hours. The illness began with a sort of sudden stupefaction of the children. The respiration became hoarse, accompanied with groaning and occasional foaming at the mouth. The change in the blood was remarkable. Dr. Winckel made incisions in some cases, but it was only by using pressure that he was able to squeeze out any blood. It was a thick, brown-black fluid, of the consistency of syrup. The body became flacid, the liver much swollen; presently convulsions supervened, during one of which the child expired. The President of the Congress, Privy Councillor Dr. Gerhardt, of Wurzburg, suggested that this new disorder should be designated "Winckel's disease." Another disease has become apparent in the heart of a very crowded portion of London. It is a new form of Cyprus fever, and a diagnosis of a recent malignant case shows the patient to be suffering from hallucinations and lowered vitality. The faculty ascribe the disease to impure water, and have given it the name of detophobia, and, though it is seldom fatal, the sufferer remains but a shadow of his former self.

BLACKBERRY ROOT GOOD FOR SUMMER COMPLAINT.—We have great faith in a decoction of fresh blackberry root for looseness of the bowels. Last summer it completely cured a severe case of chronic diarrhoea, after the other remedies of the best physicians had proved unavailing, and it invariably cured in many other cases where it was afterward recommended. Dig the green roots, rejecting those that are large and woody. Wash thoroughly clean, and steep in water at the rate of a quart to half a pound of the root, boil down one-half and then strain or pour off. Put the liquid in a bottle with about one-eighth of its bulk of brandy, whisky, or alcohol, to keep it from souring, and cork tight. A tablespoonful of this, rather less for a child, is to be taken three or four times a day, say before each meal time. We would not go from home, especially southward, without taking this preparation along. The blackberry brandies or cordials made from the berries are of little account as remedies for the diarrhoea. The virtue lies in the roots, not in the berries.—*Agriculturist.*

CARBOLIC ACID INHALATION.—The inhalation of carbolio acid spray (two per cent. solution) in phthisis has been tried in the Mount Sinai Hospital, New York. The first case had fetid expectoration, with an average temperature of 102°. The first effect of the inhalation was to increase to a marked extent the sputa, but at the same time to check the fever. The most important effect of the inhalations was to decrease the temperature from 102° to 101°, 100°, and 99°. In some of the cases carbolio acid acted as an irritant, giving rise to considerable spasmodic effects, and in these cases calcylic acid was substituted. The latter agent did not produce such a decided effect on the temperature, but its action on the fever was equally marked.—*Medical Times.*

The Week.

Mining in the field, without startling developments or other cause of excitement, is everywhere making good, and in some localities very rapid progress. In some portions of Trans-Sierra California there is an unusual activity. The mineral belt, reaching from the headwaters of Walker river south for a hundred miles or more, including the Bodie, Dunderberg, Esmeralda, Alpine, Lake, and other districts, is becoming a very attractive and lively mining region, the importance of which seems to grow with the explorations made along it; while the fine gold-bearing ores and the bullion product of the Bodie district have earned for it a well-deserved notoriety. There are other mining centers along this belt that promise to develop, under active exploitation, a wealth nearly as large and quite as permanent as Bodie. On the upper confuents of the main Walker, some rich gold veins are being opened. The Dunderberg mine, lying near the West Fork of that river, is a property of immense value, idle now by reason of the financial troubles of the principal owner. In the big prospecting shaft being sunk at Aurora, encouraging prospects are being obtained; while the Mammoth mine, in the Lake district, though yet comparatively young, is making large shipments of bullion.

Looking nearer home, there is observable much activity in our drift and hydraulic mines, more especially in Trinity, Sierra and Nevada counties. Along and near the mother lode of California, quartz mining is undergoing a marked revival—this industry being particularly lively in Mariposa, Tuolumne and Amador counties—where many of the older mines show great improvement, and new ore-finds of importance are being made. From that section of the great Veta Madre reaching from Jacksonville to Plymouth, including the Keystone, the Oneida, the Amador, Potosi, Phoenix and other historic properties, the most encouraging reports come to hand.

The Fourteenth Industrial exhibition of the Mechanics' fair opened in this city on the 5th inst., under auspices promising a creditable and successful display of our industrial, inventive and art productions.

A Generation of Active Mining.

It is 30 years the present summer since the gold seeking population began to arrive freely in California. The Marshall-Wimmer discovery occurred 16 months before; but for a year or more following that event the only accessions made to the population previously in the country came from Oregon, the Sandwich Islands, the sea-board towns of Central and South America, and from northwestern Mexico. On the 28th day of February '49, the steamship *California* entered the harbor of San Francisco, bringing the first lot of immigrants that reached here from the Atlantic side of the continent, no sailing vessels having as yet come out around Cape Horn, nor had any immigrants arrived across the plains. Along in the spring a few sailing vessels from Eastern ports began to put in an appearance at San Francisco, these arrivals increasing rapidly as the summer advanced. As the most of their passengers made their way at once to the diggings, the earlier settled camps began then to fill up rapidly, and soon over-flowed with population.

In the month of July the advance of the overland immigration began to arrive in the mine, quite a large number of these hardy pioneers having reached Hangtown, Coloma and other camps near the terminus of the main route, by the end of August. Meantime, the arrivals by sea and overland from Oregon and Mexico had rapidly increased, and, pouring into the mines, the new industrial era with its tumult and bustle, its excitements and its excesses, was duly inaugurated. In all that was least commendable and most characteristic that era has ended. It brought with it much of evil and much of good, the latter having been perhaps a little under estimated.

The period of active mining in California having been so rounded into a full generation, its history invites retrospection, there being much in it with which the on-coming age is not very familiar. Upon the news of the discovery of gold spreading abroad, there at once ensued such an emigration movement as the world never before saw, and as it will probably never see again. This movement extended to all the people in Christendom, and to some outside. All came; the Kanaka, the Fijian and the Mongolian—the Mahomedan, the Pagan and the Christian. It was a new crusade, the masses being now impelled by a lust for gold, and not as aforetime by a spirit of chivalry or a pious desire to wrest the Holy Sepulcher from the hand of the unbeliever.

And so a stream of immigration sets toward this coast from all lands, the adventurers coming by every available means of conveyance; not a few who had essayed to make in wagons the journey overland being compelled to finish it on foot. Many perished on the way; some by disease, some overcome by exposure and toil, and some by the merciless hand of the savage. But these were so comparatively few that they were not missed, save perhaps in the hearts and the homes that their loss may have made desolate. Their goal of promise reached, the eager thousands rushed to the mines, and swarming through the gulches of the foothills awakened there for the first time the roar of a great industry.

And then for seven or eight years the work of gold seeking and gold gathering went on actively and prosperously, some meeting with a great, some with a moderate, and some with but an indifferent success. The majority of the fortunate ones taking their easily acquired gains, left and came not back again. Some of the peculiarly unfortunate, disheartened and homesick, left also and never more, or but rarely, revisited California. Those that remained and made permanent homes here, consisted mainly of such as had earned enough to encourage them to hold on, and yet not enough to satisfy their desires and induce them to return to their old homes. Hence happens it that of the Argonauts who have staid with us the most have been those who prospered but moderately at first, and so were here detained till they got well weaned from their old homes and partially reconciled to the new. Staying on, these pioneers, to adopt the foreign view of their case, became at last so demoralized that they lost all zest for civilization, and may now be considered hopelessly attached to California.

At the end of these seven or eight years, the more superficial places having been pretty well dug out, gold mining began to wane, and many of the miners leaving, the interior towns went to decay; trade diminished and all other branches of business suffered a corresponding depression. As before stated, but few of the Argonauts proper came here to stay. Their sole purpose was to gather all the gold they could within a limited space of time and leave. If they staid longer than the period proposed it was, as a general thing, because they could not help it. Hence they took little interest at first in the advancement of the country socially or materially. Most of the improvements undertaken were made in a rude and hasty manner. And, although the mines were opened and worked with a determination and energy never surpassed, it was an abnormal energy, alike unnatural and unhealthy. With the subsidence of mining, therefore, improvements halted, and everything tended to relapse into its primeval condition; bullion production having shrunk to the while to a third of its once large proportions.

For the next 10 or 12 years gold mining made

but little progress in this State, the Frazier river, the Washoe, and other diversions of population having occurred meantime. At the end of this period the business here began to revive, and has since been improving, latterly at a very lively rate; the hydraulic gravel, the deep-lying drift deposits, and the auriferous quartz veins constituting the sites of this greater activity. In these several departments our resources are likely to prove extensive and permanent, yielding large and steady profits for a long time to come. Our stores of mineral wealth surpass, in fact, the most sanguine hopes of the early gold-seekers, though more labor and skill is now required to make them practically available.

To mining in the past, or rather to the men who carried it on, we of to-day owe a great deal. They were guilty of some excesses and fell into some errors, but these were due in good part to their surroundings, and the inherent difficulties of the business, which contained much that could be found out only by costly experiments and crucial trials. During these days of learning and testing they made sacrifices for which they will never be paid. But no generation works for itself alone, nor can any great industry be advanced to a high perfection without losses and failures. They who come after these pioneers will profit largely by their unrewarded labors—profit almost as much by their mistakes as by their improvements; they will leave to their successors a noble heritage in their experience alone.

Collecting Sulphurets in Seam Diggings.

From W. H. Howland, a practical miner of long experience, we obtain the following information in regard to the business of collecting the auriferous sulphurets from the hydraulic tailings and other containing matter, now beginning to be prosecuted by new methods and on quite an extended scale. Mr. Howland, who is an inventor as well as miner, conceived the idea not long since of passing that class of these tailings that have accumulated in the seam diggings through an ordinary rock-breaker, reducing them to about the size of peas or smaller, and thereby releasing the sulphurets, which they carry in great abundance. What are known as seam diggings consist of very thin veins of partially decomposed gold-bearing quartz, running, generally in great numbers, through the slate or other formation, the principal site of these deposits being the northern parts of El Dorado county. These small veins having in times past been quite largely worked, considerable quantities of tailings have gathered at points where this class of operations was carried on. These veins were washed down by the hydraulic method, being broken up with picks or shattered with powder when too hard to be torn to pieces with the force of water, as always happened when followed much below the surface. These tailings are composed of fragments of quartz, slate, porphyry and gravel mixed with a little mud and sand. This mass of stuff, being shoveled or run into the sluice, is carried down and discharged into the rock-breaker placed at its lower end, and, passing through, is by it crushed to the fineness above mentioned. After passing through the rock-breaker the whole mass is run through another string of sluices provided with suitable appliances for concentrating the sulphurets and saving the free gold, quicksilver and amalgam, which these tailings carry in greater or less quantity.

The locality selected by Mr. Howland for his first experiment with this waste, and as heretofore supposed worthless material, is what was formerly known as the French mine, situated at Greenwood, an old camp on the Georgetown divide, and at a point about half way between the South and the Middle Fork of the American river. This place was chosen, not that the tailings were here richer than elsewhere, but because there were enough of them and the facilities for conducting the proposed experiment were good.

As the result of a first trial Mr. Howland finds these sulphurets to be more abundant and of better quality than was expected. The tailings also carry more free gold, quicksilver and amalgam than was at first counted upon. One lot of sulphurets brought to this city was found to assay at the rate of \$1,300 per ton, another lot, more carefully concentrated, having assayed as much as \$5,308 per ton. These concentrations are being treated at the Deetkin works by the chlorination process, under a guarantee to return 90% of their assay value, the price charged for working them being \$35 per ton. Mr. Howland has invented and has now in use a patent riffle especially suited for reworking this class of tailings, the sulphurets being concentrated and all their other valuable contents saved by it with great closeness. This ingenious and useful contrivance will be more fully described in our next issue.

On looking around our informant observed considerable quantities of tailings on the old dump piles in the neighborhood where he is operating, and some of which are probably as good as those he has been handling. They run uneven, however, wherever the mines themselves have been rich this refuse being found of corresponding grade. There are left here, too, still in place, many of these thin seams of quartz that appear to be full of sulphurets, and most likely contain also some free gold. They invite attention as presenting fair chances for profitable mining on a small scale.

Colorado Exaggerations.

There is no question that great wealth exists in the ground in Colorado, but the ease with which the precious minerals are reduced, coupled with the money that has been made on small investments, has blinded the eyes, and brought about fabulous statements, which demonstrate that human nature is the same all the world over. We are, in fact, children of greater growth, and our imaginations continually mislead us, particularly when glittering gold and silver is the object in the mind's eye. The Leadville fever which seized upon the mining communities of Colorado, and the heretofore cool way of talking about millions, or hundreds of thousands of dollars, has been enough to turn the brain of every man who has not gone there fully determined to preserve his equanimity.

The annual output of Leadville alone, has been estimated at one hundred millions of dollars, a few tens of millions more or less, with millions in sight is of no consequence.

These reports of the carbonate belt are freely circulated, and accredited as true, yet they are not based upon accurate information. The managers of the largest mines and the superintendents of the smelting works could not have given such information, because they could not have stopped to reckon up the output of the principal mines, the product of which is only approximately known.

Nearly all the ore produced in this camp is smelted in and about Leadville. A few small mines, producing ore of exceptionally high grade, ship it to Omaha or Chicago to be separated and refined, but the amount thus disposed of, when compared with the entire output of the camp, is very small.

There are now in operation in Leadville eight smelting establishments, with 15 furnaces, producing, when run to their full capacity, 400 tons of ore per day. A liberal estimate per ton is an average of 100 ounces of silver, and if all these smelters had run to their full capacity during the last five months, they would have turned out about \$6,000,000 of bullion, but so far from this probable amount being turned out, there was only about \$2,000,000 of bullion.

Eight more smelting furnaces are being put in running, an aggregate of 12 furnaces, with reducing capacity of 400 tons of ore. All of these will make the smelting capacity of the whole camp for the last six months of the year, \$14,400,000. That is, if the ore supply equals the demand.

There is no certainty of any such yield of ore, and it is considered by good authorities, the smelters themselves, that \$8,000,000 will be about the amount of bullion to be turned out during the last six months of 1879.

There will not, in fact, be more than 10 to 12 millions of bullion from Leadville for the entire year.

These estimates are sustained not only by the statistics showing the output of the principal mines of the camp, which can be obtained with considerable accuracy, but also by the opinion of men who are best qualified to judge. Supposing Fryer hill to produce each month ore worth \$400,000, Carbonate hill \$300,000, and all other mines \$200,000 (and these are liberal estimates), the output from the first of June to the first of December would be only \$6,300,000.

A correspondent of the N. Y. *Tribune*, says: "The president of one of the largest mining companies told me that he did not think that the year's product of the camp would exceed \$6,000,000; the manager of the largest smelter thought that it might possibly reach \$12,000,000, and this was the largest estimate I have been able to obtain from anyone who is in position to express a very intelligent opinion."

The silver product of the whole State of Colorado last year, was about \$12,000,000. There will undoubtedly be some increase this year outside of the carbonate belt, but it will not be very great—two or three million dollars will probably cover it. The only carbonate mines that are yet producing are those here at Leadville. A few mines have been opened in the Ten Mile region, about fourteen miles from here, but there are no smelting works there yet, and as the charges for freight sent here have been \$20 a ton it has been impossible to ship ore to the Leadville smelters.

The same correspondent also says: "The Gunnison country, as a mining region, is as yet almost a terra incognita. Within a few weeks only has it been accessible, and last week gentlemen who returned from there reported that in crossing the range they passed through a tunnel in the snow seventy feet long. I have no doubt that rich carbonate ores have been found there, and when they are developed they may be as valuable as those about this camp. In that case wagon roads and possibly a railroad will be built into the country, smelters will be erected and silver will be produced in large quantities. But to-day the Gunnison country is producing no silver, and no matter how rich its ores may be, it will be several months before it can begin to produce. The same may be said of the North Park and of other regions where it is reported that carbonate ores have recently been found."

"In conclusion I give it as my opinion, based on the best information I have been able to obtain, that Leadville will not send to market this year more than \$10,000,000 or \$11,000,000 worth of silver, and that the product of the State of Colorado will not be more than \$25,000,000."

Hydraulic Tailings.

Locality, Quantity and Plans for Utilizing Them.

If under our present system of hydraulic washing we are rapidly exhausting our placer mines, so are we at the same time to some extent recreating them. If the auriferous gravel banks are fast disappearing before the powerful streams played upon them, much of the disintegrated mass, after being washed and deprived of a portion of the gold it contained, finds lodgment along the beds of the outletting rivers and gulches, creating there a species of mines of secondary formation. To this residuum from the gold-bearing earth once washed various terms have been applied, those most in use being tailings, debris, slums and sliakens, the latter a name as outlandish as it is unmeaning and useless. While these sedimentary deposits are of immense extent, filling the outletting channels mentioned to a great depth for many miles, only a small portion thereof exists under such circumstances as render their profitable rehandling possible. There are millions and even hundreds of millions of cubic yards of this stuff with which nothing can in this manner be done to advantage. Only in a few localities, in fact, are the conditions such as would render a rewashing of these tailings remunerative, or with our present appliances even practicable on anything like an extensive scale. These localities, omitting deposits of lesser magnitude and beginning at the north, consist of the Slate Creek basin in Sierra county, the upper portion of Bear river and its tributaries, Indian canyon and Shirt-tail canyon, the latter two situated on the Forest Hill divide in Placer county. With the vastly greater quantity of these tailings lodged along Feather river, in the bed of the main Yuba and along the lower Bear river, nothing in the present condition of this branch of mining can be done, there being nowhere outlet with sufficient fall for running them off. The day may come when, through the use of powerful dredgers or other style of elevators, yet to be invented, much of this material can be made available for mining purposes. A great deal of it will, however, be found too poor to be thus utilized, since the farther it has been carried down stream the less gold it contains. The broad expanse of this debris that rests for 25 miles along the Yuba and for twice that distance along Bear river, and an aggregate of 100 miles along Feather river and other streams that traverse the central mining counties, will probably be left undisturbed by the irrepressible gold seeker, to accumulate until it shall have spread out into broad alluvial bottoms suitable for the use of the horticulturist and farmer, who will some day come to occupy and improve them.

Localities of Principal Deposits—Slate Creek Basin.

While there is a great deal of hydraulic mining being carried on in Trinity, Siskiyou, and other of the more northerly counties of the State, we find no very extensive deposits of this debris further north than Slate creek, Sierra county. At points beyond, most of the hydraulic mines empty their tailings directly into the Trinity, Klamath or other large, swift-running streams, which, at the high stages of water that occur every spring, sweep them away. In the counties farther south the most of these mines discharge into gulches and ravines where much of this stuff remains, there not being sufficient water here to carry it on into the larger streams.

The quantity of mining debris that has settled and been left in the bed of Slate creek is large, the main body extending along it with an average width of 200 and a depth of 50 feet, for a distance of twenty miles or more. The material here is rich, having come in from camps noted for their large production of gold, and afterwards undergone constant concentration through the agency of the floods that annually occur along these mountain streams. On each side of this creek runs a rich gravel range or dead-river, which, for more than a quarter of a century, has been the site of many exceedingly productive drift and hydraulic mining operations, the whole tributary to this stream. During all this time Slate creek has been the receptacle for these valuable tailings, which would have been carried off into the North Yuba, into which this creek empties, but for the rocky barrier across the latter at a point near Rabbit creek. To this obstruction mainly their retention has been due. With its removal, or a sufficient passage made through it, this material could be run off and be subjected to another washing, and thus made to surrender the large amount of gold, sulphurets, quicksilver and amalgam it is known to contain. Fortunately the creek, immediately below this impediment, makes a rapid fall, affording ample escape for the debris above were it once moved through the cutting away of this rocky barrier, a work that could be accomplished at a comparatively small cost.

Of the bed of Slate creek the Alturas Gold mining company own and are in possession of three and one-quarter miles. As their claim includes the falls alluded to, they control the only point of outlet for both the gravel channels

mentioned and the entire basin above. Already this company, availing themselves through means of a tunnel of some slight fall at Port Wine bridge, have attempted a rehandling of the tailings on their ground, but were soon forced to suspend operations, the descent below their sluices being insufficient to keep them free. In order to get the necessary grade and prosecute washing without further interruption, they now purpose making an open cut through the reef near the lower end of their claim; a work that will require but a few months and a comparatively moderate outlay of money for its completion. With a view to expediting the business, this company, which is made up of men of limited means, would be glad to exchange a part interest in the property for a fair cash equivalent. As the enterprise cannot fail to prove profitable, their offer ought to meet with ready acceptance at the hands of those having money to spare. In the entire range of our mining industries it would be impossible to find a better opportunity for the safe and profitable investment of money, since in no other have we so much absolutely certain data to go on before hand. Here cost and profit can be estimated in advance with much closeness. The amount of the material to be handled can be measured and its value, cost of treatment and probable returns calculated at the outset with approximate exactness. Such a thing as financial failure or even serious disappointment could hardly occur in an undertaking of this kind without gross, and we may say, intentional mismanagement.

The Alturas company have completed all necessary surveys, drafted maps and diagrams illustrative of the ground, planned the work and estimated its cost, and, in short, perfected all preliminary labor, being now ready to com-

sluices, tunnel, river bed, tailing deposits and other features of the property and projected improvements, this company having expended some \$20,000 on these preliminary labors. Their proposed tunnel, which will be two miles in length, starting on Bear river at a point about one mile above Colfax, will penetrate the ridge and open on the North Fork of the American river several hundred feet above its head. Through this tunnel all the tailings in the various channels above the point where it starts in could be run off and emptied into the North Fork, which lies about 1,000 feet lower than Bear river. The great objection to this project is its cost, estimated at something over half a million dollars. Still, even under such an expenditure, the investment would no doubt prove a good one, as the material to be handled here is of excellent grade and vast in amount, the supply being in fact so great that with the contributions made by the hydraulic mines above it can never run short. As the tunnel projected by the other company would be less than one mile in length, the cost preliminary to getting under way would be greatly less with them than with their neighbors below. They would not, however, have so large a stock of material to draw on, though no doubt enough for all practical purposes. One or both of these schemes will probably soon be carried into effect, as these companies are now making strenuous efforts to that end.

Indian and Shirt-tail Canyons.

The quantity of tailings lodged in these canyons as compared with that in Bear river is inconsiderable, still there is a sufficiency of them and, what is quite as important, they are of superior quality. Estimating the amount in a rough way, it may be said that each of these re-

GROUND PLAN OF MISSION ROCK GRAIN WAREHOUSE.

mence actual operations, which they are anxious should be pushed diligently and with the largest means they can command during the coming dry season. To explain in detail their proposed plans of operating would require more space than can here be spared. Suffice to say these plans have been matured by skillful engineers, aided by the experience of practical miners, and will no doubt fully answer the purposes intended.

Bear River and its Tributaries.

Along Bear river and its upper confluent is to be found the greatest extent of hydraulic debris met with anywhere in the State, the material lodged along these various streams covering a linear stretch of more than a hundred miles. Fifty miles of this stuff, comprising all that lying along the lower section of the main river, will be likely to escape invasion by the gold hunter, there being no way whereby it can be again washed without being first raised through mechanical means, a process which it is not rich enough to justify. For moving the debris lying further up, including that in the main river as well as its branches, a tunnel will have to be run through the ridge that separates Bear river from the north fork of the American. Two companies have been formed for constructing each an outlet of this kind, the one designated the Bear River Tunnel, Fluming and Mining Co., and the other the Bear River Tunnel Co. The former, organized some five or six years ago, has since secured by location or purchase large sections of these tailings, some lying along the main stream and some along Greenhorn canyon, Steep Hollow and other of its branches. This company has procured to be made by some of our most competent and trustworthy mining engineers thorough examinations of all parts of their property, the results of which have been embodied in elaborate reports abounding with carefully prepared and well arranged data. Accompanying these reports are elegant maps drafted on a large scale and showing surveys made, with diagrams exhibiting longitudinal and cross sections, elevations, grade, etc., of the

ceptacles contains a body of tailings 100 feet wide, 50 feet deep and some six or eight miles in length. To move them a rocky obstruction similar to that in Slate creek will have to be cut through, the fall below this point being in each case ample to prevent their again making lodgment before reaching the North Fork of the American river, into which these canyons discharge. The owners of Indian canyon are now engaged making the necessary opening for running off its contents, and are reported nearly ready for active operations. The owners of the other deposit are also said to be moving with a view to utilizing the same, and as they are possessed of ample means, the work, if once entered upon, will be likely to meet with early consummation.

METEOROLOGICAL SUMMARY FOR JULY.—The report of the United States Signal Service officer, of San Francisco, for the month of July, is summarized as follows: The mean height of barometer for the month was 29.934; mean temperature 58; mean humidity, 78.2; prevailing winds, west; highest barometer, 30.093; lowest, 29.30; highest temperature, 76°; lowest, 51°; monthly range, 15°; greatest velocity of wind, 30 miles per hour; total number of miles traveled by wind, 9,143; total rainfall, .01 inches. Rainfall in July during former years: 1872, .01 inches; 1873, .01 inches; 1874, .00 inches; 1875, .00 inches; 1876, .01 inches; 1877, .02 inches; 1878, .01 inches.

Of a grand total of 94,842 men in the British army, 62,860 belong to the Church of England, 20,872 are Roman Catholics, 7,125 Presbyterians and 3,985 of other denominations.

The coinage of standard silver dollars will this month fall \$500,000 or \$700,000 short of the minimum amount fixed by law.

The Cornish mines have been worked for over 1,000 years, and are entirely exhausted.

A Mammoth Grain Depot.

In San Francisco, from which point our bulk of the grain is shipped, huge warehouses are placed at available points on the city front, convenient to the shipping, and in positions where grain may be landed from barges without too much handling. The most extensive and complete enterprise of this character is the warehouse and grain depot, owned by the California Dry Dock Company, and situated on Mission rock, an island about 600 yards from the city front, near the Pacific Mail Steamship Co.'s wharves.

The whole property owned by the company aggregates 14 acres, of which 8½ acres are covered by wharves, the warehouses covering over 2½ acres. At any point of the wharf there is sufficient depth of water to load and float the largest ships at extreme low water, and the warehouses are accessible to receive or ship grain from all sides. There is room at the wharves to accommodate a dozen large ships at one time. The company have a small steam ferry boat, making half-hourly trips, free, to and from the landing at foot of Second street.

We made a visit to the warehouses recently and were impressed by their great size and the extreme neatness and thoroughness of the structures and all their appointments. An engraving showing a plan view is given herewith, which will give an idea of the position of buildings, etc., to those who have not seen it. At convenient points encircling the warehouses are placed tanks, numbered 1 in the engraving, which are kept filled with water for the extinguishment of fire. Rows of fire buckets are placed about in different directions. The engine houses (marked 2) are intended for sheltering the hoisting engines when not in use, these engines being used for loading or discharging cargoes. The office of the Superintendent is marked 3. The grader is marked 4, and engine and boiler rooms for grader 5.

This grader, as it is called, is the only appliance of the kind on the coast, and was but recently introduced here. This new and improved machinery, for cleaning and grading wheat for export, has a capacity of 50 tons per hour.

It is well known that the San Francisco Produce Exchange have a standard of Nos. 1, 2 and 3, by which grain is bought and sold, according to quality. This grader is intended for producing either of these grades, according to the desire of the owner. For instance, a buyer purchases a number of lots of wheat, some good and some poor, some dirty and some clean. He may have seven or eight varieties. From his samples he makes a grade which suits him, and then directs the Superintendent of the warehouse to grade the wheat in accordance with the samples sent. That is, take two sacks of the first class, three of second, eight or nine of the third, and so on. The proportionate quantity of each lot is put into the grader. This machine takes the grain, mixes it thoroughly, takes out more or less dirt, chaff, straw, etc., so as to bring the hatch to the required grade. If it is wanted thoroughly clean, it can be made so. If only a second or third grade is wanted, the machine is arranged to take out more or less foreign substances as desired.

The wheat is put into a hopper and elevated to the top, where it falls into a series of shaking screens where it is cleaned and mixed, and comes out below again prepared to required grade, and is then sacked for market. Buyers can in this way average their purchases so as to bring them to suitable standards. This machine is also available for cleaning wheat where it is not desired to grade it.

Grain stored in these warehouses is always accessible to market and high rates may be obtained at all times. The warehouses are light, airy, clean and free from rats. Danger of fire is very slight, the fire insurance being only 1½ per annum. Grain consigned to this company by water is insured in open policy at special rates. Wheat shipped by railroad via Stockton care of the California Steam Navigation Company will be received by them at Stockton and delivered at Mission Rock Warehouse at same rate of freight as to Oakland wharf.

Season storage ending June 1st, 1880, is \$1 per ton. Short rates of storage are, for first month, 30 cents per ton, or 40 cents per ton, if delivered. Each month thereafter, 20 cents per ton. The weighing in, is free, but weighing out is charged 10 cents per ton.

The company are prepared to advance money at bottom rates, with interest payable at end of loan. Freight is paid, and fire insurance and loans are effected free of commission. The premises of this company are a model of neatness, and it is really worth a visit to inspect the mammoth warehouse and grain depot of the coast. The little ferry steamer carries passengers free, and Mr. Sinclair, the Superintendent, will take pleasure in showing visitors around. The wharves are built over the old Mission rock, and the area under the warehouses is filled in so that the superstructure is solid and substantial. The officers of the company owning this property are, Oliver Eldridge, President; W. C. Gibbs, Secretary; and Chas. H. Sinclair, Superintendent. The office is 318 California street. The entire storage capacity for grain, at present, is 40,000 tons, which can be easily increased.

No appointment for the English Mission is expected to be made until Minister Welch returns home.

Improved Grounds For Sale NEAR SAN JOSE.

The subscriber offers for sale a tract of land, 40 acres in extent, located half a mile south of the road from San Jose to Alum Rock, and four miles from San Jose—directly in the warm belt of the foothills. The grounds are pleasantly and conveniently located, and under a high state of cultivation.

Five Acres in Orchard,

—CONSISTING OF—

Orange, Lemon and Lime Trees, Nuts, FIGS, BANANAS,

Together with a great variety of other Fruits, large and small, and GRAPES. The Banana ripens readily in this locality. TWO ACRES are set off for an

ORNAMENTAL GARDEN,

Which is now filled with Shrubs, Flowers, and a fine growth of ORNAMENTAL TREES, 170 in number, now 10 years old. In connection with these grounds there is now a

Small Cottage and Farm House,

Well built and hard finished. On the higher ground there is a FISH POND,

40 by 80 feet in extent, and 3 feet deep, well stocked with Carp and Trout. The pond is supplied with water from a never-failing spring a few feet distant, which delivers 24,000 gallons of water every 24 hours the year round. The pond is at an elevation of 20 feet above the house, and from it pipes are laid for irrigating the orchard and garden, and supplying the house. The balance of the place is now devoted to grass and grain, but may be improved for orcharding or other cultivation if desired. This place affords a rare opportunity for anyone desirous of securing a well-improved locality for an elegant country residence, and will be sold at a great bargain. For further information apply either at this office or of the proprietor on the premises.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

SANDERSON BROS. & CO.'S

Best Refined Cast-Steel.

Warranted Most Superior for Drills, Hammers, Etc.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock and for sale

At No. 417 Market St., S. F., - H. D. Morris, Agent.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature, thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Cross and Blackwell, London &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

THE ELKINS

"BOSS" GOLD AMALGAMATOR.

Is the Best, Simplest and Cheapest Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 160 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 1-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

INVENTORS

Will find it to their advantage to call on us at 328 BUSH STREET, bet. Montgomery and Kearny, (up-stairs.) S. F.

[CONTINUED FROM PAGE 85.]

few days ago, carrying free gold from rock down three ft. The rock assayed \$3,400. The Gold Fleece, located at Picayune gulch, two miles from Animas forks, produced surface gold assaying as follows: Gold, 8,551 ounces; silver, \$161,420; silver, 5,598 ounces; coin value, \$5,209 76; total, \$167,289.76. From 300 pounds of second-class ore was obtained, by mill run: Gold, 10 ounces; silver, 53 ounces. From 1,200 pounds third-class ore was obtained: Gold, 5 ounces; silver, 41 ounces. The Golden King, an extension of the Golden Fleece, produces ore from pay streak 12 inches wide, assaying: Gold, 3 ounces, value, \$52.01; silver, 417 ounces, value, \$492.06; total, \$544.07. At Mineral Point the mines are active, with good ore on most of the dumps. In the San Miguel district the Lena, at present working, shows a pay streak of high grade copper, assaying 300 ounces in silver per ton, with a trace of gold. In the Diamond tunnel the vein is over four ft wide, carrying good ore the entire width. From the Susquehanna 13 tons were sampled and promise at least 250 ounces to the ton. From the Aspen mine 100 tons of ore have been taken that will average 175 ounces in silver per ton. Rich float has been found in Hensen creek, near the Burro vein, indicating the existence of a valuable silver-bearing vein.

CLARK CREEK COUNTY.—The Dunkirk has a body of ground leased and is sinking on a vein of ore from a foot to 16 inches in width. This is principally fine-grained galena, no runs of which have yet been taken, but assays range from 640 to 1,790 ounces of silver per ton. The breast of the drift, which is a short distance west of the shaft just commenced, carries a fine body of ore of the same quality. The Pelican mine has a shaft sunk 150 ft east of the tunnel to a depth of 160 ft, this being the lowest point yet reached in the mine. Sixty ft below the tunnel level is a level run 600 ft west from the shaft; and at the west end of the same, a couple of men are drifting on from six to eight inches of ore carrying ruby silver and gray copper. There is considerable ore all along the lowest level, and the shaft also carries a fine body of mineral. Ore mills as high as 300 ounces. In the Little Annie the surface outcrop is distinctly visible for a distance of 3,000 ft, and gives unmistakable evidence of a strong fissure vein. The ore taken out of the discovery shaft ranged from 200 to 700 ounces per ton, carrying sulphurets and silver glance, but consisting mainly of galena. In the O K lode the ore streak is from two to three inches in width and consists of galena and gray copper, and outside of this there is some scattered ore carrying gray copper and ruby silver. The ore of the Isothermal assays from 300 to 800 ounces, and the crevice is from 20 to 30 ft wide.

IDAHO.

ITEMS.—(Statesman, July 31: Considerable placer mining is going on on South Boise river, Alturas county. A run of three weeks in one of them netted \$300. The old fashioned hose and pipe are used. A man by the name of Smiley has struck a silver quartz lode, 16 miles above him, on the South Boise called Smiley's district, and taken prospects to Atlanta, which Mr. Einsfeldt has assayed, making several assays that go \$5,000 to the ton. Quartz is being taken out with great energy from the old leads at Rocky Bar.

A MAMMOTH LEAD.—Dr. J. L. Stephens gives the following description of the lead which he has located with C. Jacobs and Charles Hinder. The lead is not to exceed eight miles from town and a short distance to the right of the Idaho City road on this side of the summit. It crops out at the point of discovery, three ft high, and is from two to ten ft wide. He thinks the lead will average eight ft on the surface and can be traced three miles. They brought down rock and had two assays made; the lowest went \$25.80 and the highest \$305 to the ton in free gold. They call it the Palmer lead, and have located 3,000 ft, and 3,000 ft of extensions have already been located by other parties. Doctor Stephens says this mountain range is full of quartz, and is as good a mineral belt as there is in the Territory.

UTAH.

BINGHAM.—(Tribune, Aug. 2: Tom Sullivan struck a vein of high-grade silver in this district, a few miles south of and between the Clipperton and Bert Harro mines, and named it the Davenport. It produces ore which assays 118 ounces in silver, with a sprinkling of gold. Two miners on the sundown side of the Squash summit, have penetrated 600 ft in the Clipperton and about half that depth in the Rob Roy and other mines. Their ore is high grade. The last lot sampled 130 ounces in silver. Two arsenals worked by mule power, have lately been erected in Muddy gulch, above the Stuart mill. These, with the mill, backed up by the usual drouth, exhaust the water available in that gulch, and the company are about to bring water from Carr Fork by means of 24-inch pipes made of galvanized iron, and laid upon the surface of the ground, from a point near the Sunset mine in the last-named gulch.

Kern County Mines.

EDITORS PRESS:—After a week's traveling in this vicinity of country, I find it in a prosperous condition. There are a great many miners at work in the gold mines here, principally placer mines. Some of them are doing remarkably well. At the French mining camp in Rag gulch they average about \$6 per day to the man. There are many different camps here in which all of them are making fair wages at present, and the prospects for the future are remarkably good. There are some good ledges of gold quartz here, though none of them are being worked to any great extent. Messrs. Biggs & Garrison are at work on a quartz ledge near Whits River P. O. A few days ago they cleaned up their one-horse mill and got \$500, which pays them very well for two weeks' work. Yet they could not get all the gold with their broken, worn-out mill. Mr. T. C. White also has a rich quartz ledge, in Grizzly gulch, which undoubtedly contains a rich treasure. I also find a great many old and experienced miners here, men who have worked mines in different countries, and they say the prospect here for gold, silver and copper is as good as it is in any mining country.

A discovery of some new placer mines was made a few days since by some gentlemen from Bakersfield. They are artisan well horers. They sunk several 8-inch holes in the valleys. Where they would get a fair prospect with the auger, they would sink a shaft. It is a much easier and quicker way of finding the bedrock than to dig to it. I saw them sink a hole 22 feet in one hour. All of the miners seem to be greatly pleased with the discovery. I am forced to believe that this country will yet show to the world its hidden treasures at no distant day.

MILTON KENNEDY.

Glenville, Kern Co., Cal.

THE United States Consul at Gibraltar has been threatened with death unless \$3,000 is forthcoming.

Opening Exercises of the Fourteenth Industrial Exhibition.

An extremely large audience greeted the managers of the Mechanics' fair at the Grand Opera House Tuesday afternoon, and the attention given to the programme evinced a more than ordinary interest. Upon this stage were seated some of the representatives men of San Francisco. The exercises were opened by the rendition of the Grand Exhibition march. The orchestra, under Prof. Schultz, showed its powers as an artistic combination in its musical abilities displayed in this selection, which is an original composition of Prof. Schultz. Few selections are, in our opinion, superior to this home composition. The opening address was delivered by Irving M. Scott, Esq., in a very able manner, and his remarks were frequently applauded. The address was as follows:

The President's Address.

Ladies and Gentlemen:—The progress of mechanical arts is more wonderful than the magic power of Aladdin's lamp, and illumines the aphorism, "Truth is stranger than fiction." Bud and blossom precede the mellow fruit and golden grain; the ideal the reasoning; roseate youth, grave and philosophic age. The early conceptions of the forces of nature, and acquisitions of science, art and religion, are full of poetic imagery.

Principles properties and achievements were personified as supernatural beings.

Aeolus, Neptune, Vulcan, Minerva, Odin, Wodin and Brahma, coming to us with the must of ages, were the buds whose after fruit gave us a Christian religion with a Divine power as its center. The search for the philosopher's stone, the alchemist and a universal solvent, brought from crucible and closet truths upon which was founded the noble science of chemistry. The search for a universal remedy for all diseases, with witches' spells and incantations, has blossomed into a materia medica, founded upon a correct and intelligent diagnosis, as the only substantial basis for the treatment of disease. They who sought to forecast the future, and read their destinies in the stars with symbols and "mathematic sign," plowed the field from which astronomy reaps her golden grain. And they whose superstitions and fears translated the electric forces into Jupiter's fulminations, hurling the fiery bolts of heaven in divine wrath, wonder at the marvelous deeds of telegraph and telephone, and await the coming harvest, whose ripening grain is so full of promise. The architect, sculptor and painter of antiquity, rearing and adorning triumphal arches, mausoleums, amphitheaters and temples, were the avante couriers of

"First, unadorned and nobly plain,
The manly Doric rose;
The Ionic then, with decent matron grace,
Her airy pillow heaved;
Luxuriant, last, the rich Corinthian,
Spread her wanton wreath."

The Romans add the Tuscan and composite, and from ancient rites bloom these five unrivalled orders in mechanic art.

They who sought perpetual motion and the impossible, mingling superstition and craft with honest effort, laid the rails for the car of mechanical progress, whose telescopic eye sweeps beyond the horizon of their time; whose metallic tongue tells the world's gossip; whose analytical nose determines and defines with perfect truth all component relations; whose mechanical ear will tell the future of the present through indestructible plates; the reach of whose arms enfolds all other. And whose achievements lead her students

"Into regions yet untrod,
And read what is still unread
In the manuscript of God."

Of the seven wonders of the world, representing the advancement of antiquity in the mechanic and elegant arts, with the exception of giving employment to vast labor at the price of individual liberty, and in furnishing classic models, only the *Pharos* was, so far as known, of practical benefit. The talent, genius and study of those remote ages, seem to have been devoted largely to the art of war; luxury, ornamenting structures for games and the worship of idols.

Prior to Archimedes little progress had been made in analytical or practical mechanics. With the screw and specific gravity came the exclamation, "Give me where to stand, and I will move the earth."

The doom of Sampson: "They put out his eyes and bound him with fetters of brass and he did grind in the prison house," indicates the use of millstones to belong to a remote age. The improvements of the Romans in hydraulics—in using water to drive stamps and for mill purposes—though limited, is described by a writer of those days: "Cease ye maidens, ye who labored in the mill; sleep now and let the birds sing to the ruddy morning, for *Ceres* has commanded the water nymphs to perform your task."

The commerce of antiquity was mostly inland. The directive power of the magnet, the key of maritime commerce, was not known in Europe until late in the twelfth century, though the Chinese claim its discovery 2,634 years before the Christian era.

The agriculture of the ancients was carried on by rude implements; plowing with a crooked stick. The Romans added the colter and mold

board and iron shares. Pliny the elder states in the first century of the Christian era, in the lowlands of Gaul, large vans with projecting teeth were driven on two wheels through the standing corn, the ears of which were torn off and fell into the van. A yoke of oxen pushed it before them; this was the beginning of our modern reaper.

Pottery, porcelain and glass were in some instances carried to great perfection. Fabrics of linen and cotton date almost back to the fig-leaf. The cere cloth from Egypt comes well preserved 4,000 years old, and hemp is as old, and silk came from the Orient 2,600 years before the Christian era.

Gold, copper, bronze, and their workings, come from the earliest times. After these came the age of iron. The Huns, early Britons, Greeks and Romans used iron largely for armor and arms. The residuum of the early Roman iron furnaces in the Dean forests, England, supplied 20 furnaces one hundred years. The working of iron was considered of the first importance in the arts of civilization. Accepting the classification of Lucretius, that man's earliest arms were fingers, teeth and nails, and stones and fragments from the haunching woods; then copper next, and later the tyrant iron.

As representing three periods in the progress of a nation's development from barbarism to civilization, it will be seen the Romans had made the greatest advancement. The fall of the Roman Empire stranded the Admiral of the fleet of ages. Her vast treasures were scattered, war drank the blood of millions. One by one the lights of science, art, literature and civilization flickered and went out. Darkness settled over the world. Centuries went and came till the genius of Copernicus, Galileo, the Bernoullis, Kepler, Leibnitz and Newton, princes of philosophers, lifted the darkness and let in the light of the brightest day since the dawn of creation. The evolving the Copernican system of astronomy. The discovery of the law of falling bodies. The laws enunciated by Kepler; the laws of attraction; the principles of fluxions on the differential and integral calculus; the inventions of this telescope and time-keeper.

Problems in philosophy and mechanics, terrestrial and celestial, were resolved by the touch of a wand more potent than that of the magician. The foundations of the grandest and loftiest temple of knowledge were laid broad and deep in eternal truth. Chemistry rose from the mystic arts of the conjurors, to the dignity of science; the affinities of matter and the combining proportions of its atoms were established upon a firm basis; matter was shown subject to a change of form, but not to destructibility.

Geology rose from the hypothetical to the real, and students read from fossils, strata and formations, the history of the earth back millions of years.

The discoveries and inventions of the last three hundred years equal, if they do not exceed, those in all preceding times. Rumford discovered that "heat is a mode of motion." Chemical analysis showed matter to be indestructible. More recent investigations prove force indestructible. The heat and light of the sun stored in the coal fields ages ago is now developed in the motion of the steam engine and the electric light. The heat of the sun lifts the waters to the clouds; they fall in beneficent rain, supplying the wants of life. Every blow of the hammer, all animal movements, the heartfelt sigh, the trickling tear, the merry laugh, thought of the brain—all have their mechanical equivalent in the sun's heat.

In an enlarged view, the study and application of force in its myriad forms, taken in connection with inert matter, constitutes the province of the mechanic. His field of research is upon the land and upon the sea—in the earth and air, and in the starry heavens. Conscious that reason is heaven's richest endowment, he fearlessly follows her lead, though it be where "angels bashful look."

Printing and printing presses—the application of steam to the engine, steam navigation, reaping machines, sewing machines, locomotives and railroads—cotton and woolen goods, and their mechanical appliances, with which a child of to-day directs the motion of six thousand spindles, and makes from a pound of cotton a thread one thousand miles long, and does over six thousand times the product of the best spinster of a hundred years ago. Mark the progress of mechanical art. The telegraph, telephone, electric light, photograph and spectroscope are a few culled from the vast treasures of the world. By whose peculiar functions intelligence is communicated with the fleetness of the lightning's wings from person to person, from city to city, across continents, and through the seas. Speech in the exact intonations of the speaker's voice addresses the ear miles away, or reproduces for the time to discover the present to posterity. The electric light reappears as pure as when cycles ago it darted from its solar fire-side. The features and expression of animate and inanimate nature, terrestrial or celestial, are delineated at sight. And the composition of the sun, stars, comets, nebula, determined with the precision of chemical analysis.

Contemplating these achievements, the mind unhidden exclaims, Science! Oh, beautiful science! How delicately frail thy youth! How often was thou prostrated in the dust by the monster ignorance! But as often rose and grew in goodly proportions till now, the Nadir is thy footstool! The Zenith thy diadem and systems of rolling worlds thy toys! Atoms, myriads of suns and systems are in thy ken! And star dust in thy grasp: science,

mechanics, civilization, and their economies fellow-citizens you inherit.

And in the conflict of races their fate is in your hands, you are face to face with the problem of life on a more economic basis than Californians have hitherto submitted to, and this re-adjustment shows much chafing and discontent, which will test the principles of our pioneers. And prepares the coming generation for their task of building homes, whose social roots must be sent straight down into the soil of truth and virtue, and manly self-reliance.

We must prove our faith in ourselves by being our own customers and keep the wheels of industry moving and the hands of labor employed at home. These annual exhibits gather under one roof the aggregate product of our industries, and to the observing student mark our advancement or our decline. Beginning with the rude and fragile canoe, causing but a ripple upon the water, there have arisen, as by enchantment, vast fleets, plunging the ocean's wave in every clime, and mighty navies, whose thunders shake the foundations of rock-built cities.

These, as also the rude cabin, the cottage and palace, the halls of learning, the domed capitol of nations, the temples of justice and of worship, with their lofty and symmetrical spires, the hamlet and vast cities, the useful and ornamental, the grand and the beautiful, are all the works of the mechanic. Not an improvement in agriculture and commerce and domestic affairs, tools in manufacturing, instruments employed in any way of the learned professions thread spun, fabric wove, article made, garment or jewel worn, nor letter printed, but that it is of the works of the mechanic; the pen and sword—the p'ow and gun; the implements of peace and the implements of war are alike the works of his hands.

By his efforts this is made a *live* world; the mind, individually and collectively, is refined and elevated. Comforts are secured, and civilization rendered a fact.

The pages of history contain the declarations—I am a physician! I am a lawyer! I am a divine! Made suggestive of the old Roman's pride, in using the password of the world, *I am a Roman citizen!* But now and henceforth let the prouder password be, *I am a mechanic.*

The poem of Miss Julia Clinton Jones, "Mechanic Art," was delivered by Mr. T. W. Keene in an unapproachable manner. The poem itself is a gem, and Mr. Keene proved himself equal to the occasion.

The "Dream of Love," rendered with cornet solo by Prof. Henry Mehden and orchestra, was so beautiful that we were sorry when the finale was rendered.

Dr. Thomas Guard, delivered the oration of the 14th exhibition in an able and interesting manner, riveting the attention of the audience by his wit and by his solemn eloquence, and we are sorry our space will not admit his remarks in full.

The closing piece by the orchestra, "Overture" by Hermann, effectively concluded the opening exercises, and declared the 14th Mechanics fair open to the public.

Paying for Government Timber.

J. A. Williamson, Commissioner of Public Lands, has issued the following circular, showing how those who have cut Government timber may escape prosecution. The instructions are addressed to registers and receivers in the land offices:

The fact having been brought to the notice of the Department that many parties who have cut railroad ties, cordwood and logs upon the public wooded domain, are desirous of relieving themselves of liability to prosecution for violating the statutes relating to illegal cutting of timber, by paying for the same, you are hereby authorized and instructed to make settlement with all persons who have trespassed upon the public timber lands in your district, prior to the 17th of June, 1879, by cutting railroad ties, cordwood, or logs therefrom, and who propose to settle therefor, upon the following terms, viz: 1st. For all railroad ties, two and one-half cents per tie. 2d. For cordwood, 50 cents per cord. 3d. For logs, one dollar per 1,000 feet (board measure).

As a condition precedent to such settlement, you will require each and every person seeking the same, to submit to you a full statement, under oath, showing the time and place where the trespass was committed, and the quantity of ties, wood or logs by him, or them, taken and removed from the public lands.

If a proposition is accompanied with the statement that a portion of the ties, wood or logs was taken from railroad lands, you will not allow any deduction for that reason, except it be conclusively shown that all the trespasses for which settlement is desired were within railroad limits. You will also make special reports of each settlement thus made to this office, and will also forward a consolidated monthly report of the same.

The foregoing instructions do not apply to cases where criminal or civil suits have been instituted against the parties in interest. In such cases you will receive the propositions to settle, when conforming to the requirements above set forth, and transmit them to the U. S. District Attorney having charge of the suits, accompanying this reference with a copy of these

instructions, and a report of facts as you may find them; at the same time forwarding to this office copies of all papers sent to the U. S. Attorney, and in your monthly consolidated statement of cases noting those so referred. Nor are they to be construed as conflicting with the provisions of the act authorizing the citizens of Colorado, Nevada and the Territories to fell and remove timber on the public domain for mining and domestic purposes, approved June 31, 1878.

In cases involving a conflict of identity as to the proper party or parties to pay the stumpage rates, and in all cases of illegal cutting of logs, ties or wood upon government lands, you will seize the same and hold the property until the stumpage rates above announced are paid.

In all cases where there are costs of watching over and caring for the property, they must be embraced in the settlement and liquidated by those seeking it.

You are further instructed to report, with as much detail as practicable, any and all trespasses upon timber lands, committed after the 17th of June, 1879, that may come to your knowledge, in order that criminal proceedings may be instituted to punish the parties guilty of such trespasses.

News in Brief.

THE ZULU war cost England £4,500,000.

TURKEY is still arming the Greek frontiers.

A SERIOUS riot is reported at Philadelphia, Pa.

THE late Khedive of Egypt will reside at Rhodes.

THE increase of the public debt for July was \$6,086,344.

THE French colony in Egypt consists of 20,000 persons.

A CONFLAGRATION is raging at Ortaquei, on the Bosphorus.

MINNESOTA will harvest 44,000,000 bushels of wheat this season.

FRESH disturbances are reported in Silesia, on the Russian border.

THE failure of the Consolidated Bank at Montreal is announced.

THE Colorado beetle has made its appearance in county Cork, Ireland.

BULLION in the Bank of England increased £273,000 the past week.

BASHI-BAZOOKS are pillaging and assassinating on Bulgarian territory.

IN France, slates used in roofing are bedded in plaster on the boarding.

OTTO is about to be flooded with campaign documents from Washington.

LORILLARD's "Papoose" came in sixth in the race at Goodwood, Eng., lately.

"Lucy" won the fifth heat in the postponed pacing race at Cleveland in 2:16.

THE Tuilerie ruins are to be demolished and the site transformed into a garden.

DURING July the total coinage at the United States mints was \$4,681,610.

THE Stadacona Bank, at Quebec, will go into liquidation and wind up its affairs.

THE crops in Hungary and Galicia have been damaged by heat, followed by rain.

THE rush from New York for summer resorts is greater than at any time since 1876.

THE free postal delivery system will be established at Portland, Or., October 1st.

THE army of the Zulus is broken up, the nation dispersed and the King a fugitive.

THE condition of the currency at Constantinople is becoming more deplorable daily.

THE Custer battle field on the Little Big Horn has been made a national cemetery.

THE Government expects to prorogue the British Parliament on the 16th of August.

THE annual session of the National Educational Association has begun at Philadelphia.

A DISEASE resembling cholera is ravaging Center Point and Walker, Linn county, Iowa.

ANOTHER expedition in search of the North Pole will leave England in the spring of 1880.

THE weather is excessively warm at St. Louis, and several cases of sunstroke have occurred.

LORD DERRY's recent award as umpire affects 57,000 persons in the Durham, Eng., collieries.

THE corner-stone of the monument to Gen. Anthony Wayne was laid at Erie, Pa. August 4th.

BULLION to the amount of £500,000 was paid into the Bank of England on balance August 4th.

A SKIRMISH between United States troops and Indians occurred Saturday at Salt Lake, Texas.

HALF a score of obnoxious publications have been suppressed within the last few days at Berlin.

THE old woman who threw a stone at the King of Spain has been sent to an insane asylum.

AT Liverpool wheat is quoted at 8s 6d @ 9s 8d for average California white, and 9s 6d @ 9s 10d for club.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Hillside, July 31st, \$4,000; Alexander, August 1st, \$11,004.61; Con. Virginia, July 28th, \$47,373.07; Indian Queen, July 28th, \$4,579.16; Northern Belle, July 30th, \$8,473.44; Hillside, August 4th, \$4,200; Ophir, July 29th, \$25,464.88; Belle Isle, August 4th, \$29,000; Independence, August 4th, \$6,000; Bodie Con., July 29th, \$18,752.42; Chisty, August 2d, \$7,838; Northern Belle, August 2d, \$6,682.18; Martin White, August 3d, \$7,947.20.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

FOR THE WEEK ENDING JULY 20TH, 1879.

217,073—VEHICLE SPRINGS—E. T. Barlow, S. F.

217,085—CHIMNEY—J. Brownell, S. F.

217,087—PIPE JOINT—J. P. Culver, S. F., and T. H. Walsh, N. Y.

218,017—CLUTCH COUPLING—S. Gillekullen, S. F.

218,018—BOLT AND ROD GRIFPER—S. Gillekullen, S. F.

218,023—ELEVATOR—D. H. Haven, Portland, Ogn.

218,053—VEHICLE AXLE SKIN—P. Noder, Salt Lake City, Utah.

218,054—LOCK—F. Newhoff, S. F.

218,065—ROTARY MEASURE—A. Ritchie, S. F.

218,071—WELD TURNER—J. Sherrill, Harrisburg, Ogn.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

RECEIVED, July 12th, 1879.

Messrs. DEWEY & CO.—Gentlemen:—Have received my letters patent for the bar roller to-day. I am very much obliged to you for your prompt service, and will recommend you to all who may want your assistance. I remain yours, etc., Geo. M. King.

HOW TO STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

PRINTER'S PROOF PRESS, complete and in good working order, for sale at this office, at the low price of \$30. Call and see it.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

CIVILIZED

COUNTRIES.

SCIENTIFIC PRESS—Mining and Mechanical.

THE MINING AND SCIENTIFIC

PRESS PATENT AGENCY was estab-

lished in 1860—the first west of

the Rocky Mountains. It has

kept step with the rapid march

of mechanical improvements.

The records in its archives, its

constantly increasing library, the

accumulation of information of

special importance to our home

inventors, and the experience of

its proprietors in an extensive and

long continued personal practice

in patent business, affords them

combined advantages greater

than any other agents can possi-

bly offer to Pacific Coast inven-

tors. Circulars of advice, free.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

STEAM ENGINES, BOILERS, STAMP MILLS, FRUE VANNERS
(and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores
No. 145 Fulton St. CHICAGO, ILL.

Knight's Water Wheel,

Patented January 12th, 1875.

This wheel possesses more power for a given percentage of water than any yet offered to the public. They are in practical use in many Mills and Hoisting Works, and never fail to give entire satisfaction, which facts speak fully for their efficiency, and render further comment unnecessary.

The KNIGHT WHEEL is used in the following named Mills and Hoisting Works, to which the Public are referred:

1-Eight-foot wheel, running Oneida Co.'s Mill, Amador county, Cal.; 60 stamps. Robt Robinson, Supt.

1-Eight-foot wheel, running Con. Amador Mining Co.'s Mill, Amador county, Cal.; 40 stamps and two Hepburn pans. David Davis, Supt.

1-Eight-foot wheel, running Lincoln Gold Mining Co.'s Mill, Amador County, Cal.; 40 stamps.

1-Eight-foot wheel running pump at same company's mine. S. D. R. Stewart, Supt.

1-Eight-foot wheel, running Keystone Con. Mining Co.'s Mill, Amador county, Cal.; 40 stamps.

2-Four and one-half foot wheels, used in hoisting by reversible water power at same company's mine. O. C. Hewitt, Supt.

1-Four and one-half foot wheel, running Original Co.'s Mill, Amador County, Cal.; 40 stamps, one pan, one rock-breaker. J. R. Johns, Supt.

1-Four-foot wheel, running Gover Mining Co.'s new mill, Amador county, Cal.; 20 stamps.

1-Eight-foot wheel, running same company's old mill; 10 stamps. John Palmer, Supt.

1-Six-foot wheel, running Tallman Mining Co.'s Mill, Amador county, Cal.; 10 stamps.

1-Eight-foot wheel, hoisting and driving pump at same company's mine. John Tregloan, Supt.

1-Four and one-half foot wheel, running Bunker Hill Mining Co.'s Mill, Amador county, Cal.; 10 stamps. John Palmer, Supt.

1-Six-foot wheel, running St. Patrick's Mill, Newcastle, Placer county, Cal.; 15 stamps. Jno. Townsend, Supt.

1-Eight foot wheel, hoisting and running pump, compressor and hoisting at Sheba Silver Mining Co.'s mine, State of Nevada.

1-Four and one-half foot wheel, running Luck Q. M. Co.'s Mill; 10 stamps; Oregon.

1-Four and one-half foot wheel, running Republic Mill, Nevada county, Cal.; 20 stamps. E. H. Dyer, Supt.

1-Six-foot water wheel running at the Plumas Eureka Mill, Cal.; 48 stamps, 2 pans, 9 ore-breakers and 22 concentrators.

1-Eight-foot water wheel running 40 stamps for the same Company. Wm. Johns, Supt.

4-Six-foot water wheels running the Sierra Buttes Mills, Sierra Co., Cal. Wm. Johns, Supt.

2-Six-foot and 2 four and one-half-foot wheels running Soulsby G. M. Co.'s Mills, hoisting and pumping works, Sonora, Tuolumne County, Cal. J. Leechman, Supt.

1-Six-foot water wheel running Providence 20-stamp mill, Nevada City, Cal.

1-Four and one-half foot wheel running DeFrees Mill, Tuscarora District, Nevada.

1-Six-foot water wheel running 20 stamps at Julia mine, Newcastle, Placer Co., Cal. A. H. Schnabel, Prop'r.

1-Six-foot water wheel running Mammoth Mill, 30 stamps and 14 pans and ore-breakers, Mammoth Lake District, Mono Co., Cal. Clark, Supt.

Orders can be filled at short notice, or further information given, by addressing the undersigned.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

STEEL CASTINGS.

From 1-4 to 10,000 lbs. Weight.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists Free. Address

Chester Steel Castings Co.
Works, Chester, Pennsylvania, 407 Library St., Philadelphia

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - San Francisco, Cal.

RUSSELL'S AMALGAMATOR.

Patented June 25th, 1878.

SAVE YOUR GOLD

And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riddles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

No. 717 Mission Street, near Third, - - - - - SAN FRANCISCO, CAL.

Mining Machinery Depot, PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

C. C. Bitner's Apparatus for Obtaining Met-
allic Copper from its Solutions.

Patented March 18th, 1879. Will precipitate with steam in
three hours, requiring no machinery to run it. Cost of con-
structing apparatus, \$75. The old cylinder process takes
four hours to precipitate and costs from \$1,200 to \$1,500 to
construct, besides the machinery to run it. For right to use
my Precipitator address C. C. BITNER, Spenceville, Ne-
vada County, California.

THE BEST FILEHOLDER.—After having used Dewey's
patent elastic hinge fileholder for over a year past, the
News cheerfully indorses it as the best newspaper file-
holder in existence, possessing important advantages over
any and all others in use. The holders are neat, light and
convenient, and the newspapers are placed in them with
the utmost facility and least possible time and exertion.
They are the simplest, handiest and cheapest of all. Any-
body keeping files of papers in reading rooms, offices or at
home, should send at once to the proprietor, A. T.
Dewey, San Francisco, and get the only proper fileholder.
Samples by mail fifty cents.—*Gold Hill News.*

VOLUME XXXIX
Number 7.

Dry-rot in Timber.

This subject is of great importance to carpenters, ship-builders, lumbermen, and house-owners, and of curious scientific interest, has been thoroughly examined by Mr. T. A. Britton, an eminent English architect, who has exhausted nearly all source of information. He says, that to understand the nature and effects of dry-rot, we must inquire into the structure and properties of wood, which consists of a mass of slender, short fibers, with tapering ends, overlapping each other. These fibers are hollow at first, but are gradually filled by the deposition of solid matter from the sap within them.

This woody fiber, which pervades the tree from the tips of the roots to the extremities of the branches, is the chief organ of circulation. A current of sap passes upward through it, from the roots to the leaves, and another current, containing the products of leaf-action, passes back from the leaves, and is distributed for the uses of the tree. Wood grows darker as it grows older, owing to the deposit within the fibers, and reaching maturity no longer joins in the general circulation. The inner or heart wood, being fully matured and without sap, is less liable to decay than the outer sap wood,

molds of all kinds, are part of this immense group of plants that lives upon decay and fills the air with its countless myriads of spores. These germinal particles are lodged everywhere. They are as light as vapor, and abound in air, in water, in sand, in dust, ready, when warmth and moisture favor, to burst into life. The dry-rot fungi flourish upon the products of wet-rot. Different stages of decay produce food of different qualities, adapted to different species of fungi. One species takes up the process where another leaves it, and carries it further and further forward.

Dry-rot may begin its ravages in the interior of timber as easily as upon the surface. As atmospheric dust is filled with the spores of fungi, they may be conveyed by rain into the earth, absorbed by the roots of vegetables, and diffused with the sap throughout the whole plant. It is not necessary to mention the great variety of fungi originating from these atoms or spores which exist everywhere, and produce many of our malarial diseases and diphtheria. We shall refer only to those concerned in the process of dry-rot.

There are several species of fungi causing the destruction of timber, the principal being the *Merulius lacrymans* (often called the dry-rot), the most formidable enemy of timber. Wood affected by it, shows minute white threads of a cottony texture which sheds a red powder,

Drake's Cement Machine.

Our engraving represents the application of Drake's cement machine to hydraulic works. The machine itself consists of a cylinder composed of bars of metal of a suitable shape to break up the material passing through it. The cylinder is revolved, and being set on an incline, the material passes from one end to the other. A perforated pipe passing through the cylinder furnishes a constant supply of water to the material being worked. The precious metals and finer dirt passes through the bars into the sluice, while the larger rocks, etc., are discharged down a slope, or are carried away.

As applied to hydraulic mining, the mill is run by hurdy-gurdy wheel, with water, or by steam power, as desired. In working the hard gravel and cement banks, in which this country abounds, the present difficulty is in perfectly disintegrating the hard gravel in piping it into sluice boxes, so that all the gold contained therein may be saved.

This machine is set in connection with the sluice boxes, as shown in the engraving, so that all that portion which has become fine by piping or blasting, flows through a grizzly, leading under the mill to the opposite end, while the hard gravel passes into the mill, there be-

The upper engraving represents a side view of hydraulic works, indicating the position of the mill. The lower one is a plan view, looking down from above. This mill is put, preferably, as near the bank as possible, so as to save length of sluice. No attention is required after water is turned on to the hurdy-gurdy and the cylinder once set in motion. Mr. H. K. Drake may be addressed at No. 28 Sansome street, this city.

New Zealand Gold Fields.

Late news from New Zealand, through the *Thames Advertiser*, shows that trouble has been experienced by the Auckland capitalists in pumping their mines. It appears that the gold duty exacted from the mines was so large as to destroy all benefits from the product, and at a meeting of the representatives of the mining companies to obtain some relief from the payment of the gold duty, it was finally agreed to keep the pumps working to drain the mines, provided the Borough Council should contribute to the companies a certain amount per month out of the gold duty. The Council agreed to contribute the whole of their gold duty for 12 months, provided the amount did not exceed £50 per month.

The Moanataiari mine is improving. A nice

sap being the agent of destruction. Sap being composed of water, sugar, albumen, gum, etc., ferments easily and rapidly, and is the most fatal cause of decay in wood. Wherever sap is the cause of decay it is termed ordinary rot or wet-rot. Dry-rot, although so termed, can no more occur without moisture than wet-rot. The former is one of the consequences of the latter, and begins after the fermentation of the sap begins, all of the conditions are then ripe for the inroads of dry-rot. Moisture favorable to natural decay and to the growth of plants is essential to its progress. The immediate agent of destruction in the case of dry-rot is of vegetable origin, belonging to the natural group of fungi, the best known representative of which is the common mushroom. If you examine the mold on which this plant is seen to grow, you will find it penetrated with delicate, whitish, interlacing filaments, which are the vegetative system of the plant. This part of the mushroom is called the *mycelium*, and from it arises the reproductive portion which grows above the ground. The umbrella-like cap above the ground bears the minute reproductive bodies of the fungi, called spores, analogous to the seeds of common plants. The *mycelium*, or threadly interlacing portion which grows underground, and the minute microscopic spores, which are so small that thousands of them are required to form a body the size of a pin's head, are common to all fungi.

The *mycelium* is often so minute as to traverse living plants and the pores of solid wood. It grows rapidly and causes quick decay. Potato-rot, the yeast and vinegar-plants, mildews, rusts, and smuts of grain, and

which is the *Merulius*. Long before this appearance is manifested, the interior of the wood has perished, and when the cottony filaments are seen upon timber internally affected, we may be sure the apparently solid beam may be crumbled to dust between the fingers.

The first symptoms of dry-rot in timber are swelling, discoloration, moldiness, and a musty smell. As the disease advances the fibers shrink lengthwise and break, presenting many deep fissures across the wood; finally, the cohesion of the wood is utterly destroyed, and at the least disturbance crumbles into powder.

An indication of dry-rot in a damp pantry will be a coating of fine powder, like brick-dust upon the shelves and earthenware; those being the reddish spores shed by the dry-rot fungus.

The best protection against this rot, is careful seasoning. Ventilation is not of great use. Timber must be kept either entirely wet or entirely dry. Alternate dampness and dryness is fatal. Boiling and steaming is useful in getting rid of the spores and coagulating the albumen of the sap. Let the sap out, then do not permit the absorption of any moisture, and wood will not rot.

THE INCREASED DEMAND FOR CALIFORNIA WINES.—The New York Wine and Liquor Circular, of August 11th, shows the importation to this port of French still wines in July, to be nearly 111,000 gallons, besides an increase of about 250 cases, against 47,000 gallons in July, 1878. The editor says the trade with California is wonderfully extending. So far this year fully 1,000,000 gallons of wine have come from California, and 100,000 gallons of brandy.

ing disintegrated by being rolled over and over on the bars in the presence of water. The bars are made with sharp edges, being made of T iron fitted with a plate of steel, so there is practically no wear, the mutual attrition of the pieces aiding in the disintegration. The fine stuff drops between the bars into the sluice, the stones passing through the mill, and dropping from the discharges into the same sluice box, and passing on to the undercurrents below. This saves all necessity of having drops below to break up the material.

This system will allow the working of hard cement and gravel banks at the same price per yard as ordinary hydraulic gravel can be worked. Moreover, as no "drops" are required, the simple grade of a sluice box only is needed. The mass of rocks, gravel, etc., being ground over and over in the mill on its way down, is broken up much more effectually than any drop will do. The whole expense of working cement by this machine, when put in with cars, is about 25 cents per square yard, when working from one to two thousand tons per day. When put in through the sluices, some 5,000 tons a day, or more, could be put through at an expense of between two and three cents per yard, with a greatly increased result in yield of gold.

These mills are of several sizes and not expensive. Messrs. Prescott, Scott & Co., Union Iron Works, San Francisco, manufactured one of these mills of the largest size for the New York and Calaveras Mining Co. last season, and it does an enormous amount of work at little cost. They will furnish all desired information concerning the mill to those addressing them on the subject.

looking leader, supposed to be the Golden Age reef, was cut in the tunnel a short time ago. It is four feet thick. The Kuranni turns out a good quantity of fair dirt. In the Waitotahi the men are extending a drive on the No. 4 reef, 3d level. The stone is hard, but good.

Excellent gold has been obtained from the Golden Calf up to a recent date, but has been swamped by the stoppage of the pump. In the Albionia the reef in the Sons of Freedom tunnel is being cut. Rock hard, but very nice. An assay yielded one ounce to the ton. The lode is of good size and looks promising. In the Caledonian the pay dirt is of average quality. Sinking is going on on the No. 3 lode, 2d level, with gold showing all the way down.

California (Tarau): During the month Mr. Cook, the proprietor of this claim, has had two first-class returns from stuff broken from the well known black reef. The stuff is very dry and soft, and resembles a deposit of soot, and is treated very cheaply at Mr. Cook's own battery, near the claim. Portia (Karakas): About the beginning of the month a slip of earth occurred in this claim, and disclosed the existence of a first-class gold-bearing reef, which is now being worked. A small parcel crushed went an ounce to the pound weight of stone. At Ohinemuri a good deal of work is proceeding, principally by tribute parties. As a rule the Smile of Fortune (Owbaroa) tributaries are getting pay gold.

WITHIN about two weeks the New York city banks have paid into the Sub-Treasury the enormous sum of \$55,000,000 in legal tender notes, in payment for 4% bonds.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Ene

Quartz Mining Around Nevada City.

EDITORS PRESS:—It is refreshing in these dull times to run across a lively camp. The mines of Nevada City are, perhaps, making a better showing to-day, or giving a brighter promise, at least for the future, than at any previous period.

One of the main causes for the late impetus to quartz mining, is the discovery of a very large "contact vein" or lode 160 feet or more from wall to wall, better known here as the Providence belt, from the mine where the most important developments were made. This fine belt of auriferous ore crosses Deer creek, about a mile below the city, extending a considerable traceable distance on either side and consists, as made manifest by the deepest workings, of several quartz veins, running parallel within the main fissure between the slate and granite—all showing a gradual tendency to concentrate with less and less gangue—in short, a marked improvement both in the quantity and quality of the ore as a greater depth is attained. The following are the principal locations: The Nevada City, Wyoming, Champion, Merrifield, Providence, Crosby, El Capitan, Transcript, Live Yankee and others. The most of them are said to contain good bodies of ore, in some cases very rich in gold-bearing sulphurets, and promise at no distant day to become dividend-paying.

The Providence, Now down to the perpendicular depth of 1,000 feet, is looked upon here as the leading mine of the district, if not ahead of all others in the State.

Many interesting details from other reliable sources could be added to those cheerfully furnished you for publication by the company last year, all of which are withheld out of regard to an expressed wish on their part, backed by good and satisfactory reasons, that nothing in the way of special facts or figures should just at this time emanate from them. Two or three general remarks will be indulged in.

It has the first and greatest essential for a good mine—rich ore and plenty of it—and second and scarcely less important, it enjoys the strict, watchful attention of its principal owners, being worked and managed by them in person and with something of the same system and economy that the prudent merchant or manufacturer brings to bear in his line, which will account for much of its success and the stand it has taken among the best mines of the day.

The Consolidated Wyoming Has a present depth of shaft of 500 feet; length of ore chimney on 2d level, 510 feet; 3d level drifts have run 250 feet on the ore chimney, are in ore still and expect to contain much more ore than the 2d level both in thickness of ledge and length of chimney. The 4th and 5th levels both have fine ore, but are in but a short distance from the shaft. At present are running 10 stamps, but the mill capacity will be doubled by October 1st. The mine is now drained to the 5th level by a tunnel 2,000 feet long.

The Merrifield Is one of the oldest locations in the district. Lode from 2½ to 18 feet wide, encased in granite. Greatest depth of old shaft, 600 feet. The new shaft, located 1,600 feet farther north, is now down 250 feet. The mill is run the greater portion of the year by water and the remainder by steam, crushing at present 26 tons per day, the results represented to be satisfactory to the company.

The Nevada City (Formerly the Schmidt) is located on the northerly portion of the same belt and within a few hundred yards of the Providence, Wyoming and Merrifield. The present owners purchased the mine last winter, since which they have erected substantial buildings and steam hoisting works of sufficient capacity to develop the mine to the depth of several hundred feet. The mine had been previously worked a number of years, but for want of proper machinery had not been sunk much below water level. Several hundred tons of ore were taken out, milling from \$20 to \$70 per ton in fine gold, the sulphurets running from \$200 to \$600 per ton of same. The late owners have sunk an incline 150 feet and are running levels from that station. Within the past week or so they struck the ledge in this level, which shows a width of at least two feet of good rock, carrying also a large percentage of sulphurets. It is one of the most promising of the later developments, and bids fair to rank soon among the best mines of the county. Mr. J. W. Sprague, the Superintendent, will soon commence hauling ore to a custom mill for reduction. It is his intention to erect a 10-stamp mill the coming season.

The El Capitan Is situated on the south end of the Providence lode, and is represented to have the same series of veins that appear in the Providence proper. It was opened in early days by tunnel 600 feet in length to get backs of 50 feet. Heavy machinery is now on the way from New York. As soon as it arrives a shaft will be sunk to the depth of 200 feet and work pushed vigorously and systematically. It is said to be

very favorably located and has a bright future before it. It is owned by a New York company and superintended by Mr. Francis Burns, who will hereafter furnish you, no doubt, with many valuable facts in regard to the mining of this section.

A sufficient number of examples have been cited, but a very faint impression of the value of this belt of mines has been conveyed in the skeleton-like sketch here given.

We turn now to another range and to other mines that will compare favorably with some of the best of those mentioned.

The Deadwood, Located 2½ miles above Nevada City, is from 6 to 18 inches in width, lying wholly in granite. A drain tunnel, which taps the ledge at the depth of 60 feet, constantly discharging full 12 inches of water, effectually rids the mine of the greatest impediment it had to contend with near the surface. The company are now running an incline on the ledge and are at work on the 300 level. The ore for the past year or from the opening of the mine has run from \$20 to \$60, averaging \$36 per ton. The mine, until quite recently, was run under lease, paying the lessees four dividends, the first covering all the assessments, besides paying the company for royalty and the erection of hoisting works at a cost of \$3,500. The company have purchased and fitted up anew the Oriental mill, which is now in operation. The last crushing yielded at the rate of \$60 per ton, inclusive of the value of the sulphurets. The consequence is that the stock was never more firmly held, a dividend being confidently anticipated at no very distant period. The 8-stamp mill is run by water power, with the use of only 20 inches, pressure 380 feet.

The Murchie, On the opposite side of Deer creek, is opened by incline shaft to the depth of 666 feet, with four levels. Average width of lode, five feet, most of the ore for that width being extracted and worked. At present the company is taking out 40 tons per day and milling 36, the ore averaging \$30 per ton. The two lower levels are nearly virgin ground throughout and the ore represented to be of the highest grade, going into the hundreds. In addition to this very valuable property, the company are now opening up two very promising mines on the outside. The ore is conveyed from mine to mill by a tramway, 900 feet in length, at a cost of less than 10 cents per ton. They run 18 stamps and have recently put in eight of the Frue concentrators, which appear to be giving entire satisfaction. The ore is very heavy in sulphurets, running from 5% to 33% of the gross amount of ore. The loss of sulphurets by this machine is said not to exceed 15-100 of one per cent. The concentrators had been run a little upwards of 30 days, during which time they had more than paid for themselves.

The Pittsburg Mine Has a linear extent of about 3,500 feet. The greatest depth reached is 800 feet, and the usual amount of stopping and drifting going on from the 500 level to the 800 level. The lode is from six inches to two feet wide, and said to be showing well at present depth, the ore milling about \$20 per ton free gold. From five to ten tons of rock yield one ton of sulphurets worth \$100 per ton. Their 10-stamp mill and five of the Hendy concentrators are constantly running.

It is understood that the New England Mine, Now down 600 feet, has been yielding some \$10,000 per month, first-class ore going as high as \$40 per ton, exclusive of sulphurets. The Idaho and other mines at Grass Valley are believed to be doing the usual amount of work and yielding about as formerly. My stay was too short for notes.

The Ironclad Mine, The property of Mr. John Cammet, formerly of your city, is represented to be sufficiently developed, and to have enough ore in sight to keep a 10-stamp mill running a year. There is also a fine pay chute, thought to contain from \$60 to \$100 ore.

Across the Sierras by a New Route.

New Mining Districts of Fresno and Mono.

EDITORS PRESS:—Since the discovery of the valuable mineral ledges of Lake district, Mono county, on the headwaters of Owens river, the question of the shortest practicable route to same from any railroad station has been one of the highest importance to all interested in the new mines. Learning in Fresno Flats of the new route by road and trail from that point to Mammoth City for pack animals, as well as the saddle train of John S. French, former engineer in constructing the Madera flume, your correspondent concluded to ride over, examine and report upon the route, its difficulties, altitudes, etc., the new mining districts on the upper San Joaquin, in Fresno county, but a few miles northwest of Mammoth City, and cross into Mono county for a few days to see the great Mammoth mine, of which so much is being said, as well as neighboring claims near Mammoth and Pine City. For this, Mr. French and his partner, Mr. Wellman, kindly offered me every facility.

To Measure Altitudes, Mr. John Haley, Superintendent of Enterprise mine, did me the great favor to lend his aneroid barometer, a very accurate instrument of the kind, made by James How, 2 Foster Lane, Lon-

don. In his office at the mine it indicated regularly an altitude of 2,900 feet. Being well aware of the temporary effect of fluctuations in the state of the atmosphere on such instruments, I determined to carry a thermometer also, that the temperature of air might be recorded at time of observing altitudes. The accompanying table will give results in brief.

I hope these results will prove of some interest to your readers, though they must, of course, be looked upon merely as approximations, so far as distances and altitudes are concerned. Though but brief time could be taken for each observation, as the distance of some 60 miles had to be made in about 27 hours, yet there were several circumstances favorable to and confirmatory of their general accuracy. Hence, I venture to present them with some confidence that more elaborate observations and corrections by others in future will, in the main, confirm the lights here given.

These Favorable Circumstances

Are: 1. The good repute of the instrument used and its good condition at starting; 2. the fact that July 1st quite a severe thunderstorm purified the air, so that from the 4th to the 15th, the time during which the observations given in table and many others were made, the air was in a calm and uniform condition well suited to the use of the aneroid; 3. comparisons at Mammoth with an American aneroid of Mr. S. C. Farnham, Superintendent of the Don Quixote and Monte Christo mines, gave about the same altitude, 9,500 feet, for Mill City, where the Mammoth mill is located; 4. Mr. Haley's aneroid made the altitude of the mouth of shaft of the Head Light claim—the southeastern extension of the Mammoth mine—11,000 feet, which Mr. Lilien, United States Deputy Surveyor, informed me corresponds well with other measurements of neighboring heights. The distances along the trail are made out from estimates by those best acquainted with the route and from personal observations based on time and speed of transit.

Table of Altitudes, Distances, Temperature and Time.

Total Distance (Miles)	Distance Apart (Miles)	STATIONS.	Altitude (feet)	Temp. (Fahr.)	Hour.

The Saddle Train

Leaves Fresno Flats every Tuesday and Friday between 2 and 3 P. M., on arrival of the bi-weekly stage from Berenda station, arriving at Mammoth City between 5 and 6 P. M. next day. The same days a corresponding train leaves Mammoth at 5 A. M., reaching Fresno Flats about 10 A. M. Wednesdays and Saturdays. Both trains meet at a comfortable camp provided by Mr. French—otherwise dubbed the French hotel—the only night out in Beasore meadows, named after J. P. Beasore, a pioneer of these Fresno county Sierras. The general course of the route is slightly north of east. At the regular hour, July 4th, Mr. French started with three traveling companions, one of them, Mr. Whitaker, of New York, a shareholder in the Mammoth, whose congeniality and experience as a traveler added much to your correspondent's enjoyment of the trip.

At the Madera flume company's mill the aneroid enabled me to detect an error in the altitude of the site as reported to me and given in your columns in a previous letter. As shown in accompanying table it is

5,350 Feet Above Sea Level.

Over a mile, instead of 4,800, as before given me. Hence it is about 5,000 feet above Madera, and the fall in the flume, the first five miles from the mill, is over 2,000 feet. Other information since confirms this correction.

The trail is entered five or six miles beyond the mill at an elevation of 6,300 feet, and continues for, at least, 45 miles to Pine City. For this whole distance only three cabins are seen, and not even a single Indian rancheria. On the whole trip we saw no Indian, except at the two ends of the route. There is a cabin occupied by wood choppers three miles beyond the mill, one at Beasore meadows, used in summer by Hildreth's vaqueros looking after about 500 head of cattle he keeps there, and an unfinished one in Pott's meadow, five miles west of Pine City. Few lonelier routes of travel can be found in California.

Lookout Point

Commands a fine view of the San Joaquin plains on a clear day. Fresno dome towers up to a height of about 10,000 feet very near this part of the trail.

When we left Beasore meadows at 5 A. M., July 5th, the thermometer in the open air at 32°, and frost was forming. Temperature of spring water was 42°. At many points along the last day's ride, of 40 miles, the scenery is very varied and truly grand. The best views are from the

ridge west of Granite creek, the top of West North Fork hill, the ascent to Pumice Stone gap, and from the notch of the gap in every direction. I shall attempt here no description of the really

Magnificent Panorama

Of canyons and domes, and snow-covered peaks and ridges, that is constantly unrolling itself before the eye of the delighted traveler. It must be seen to be fully appreciated. Tourists and students of nature will do well to try the route. From the table you will see that the descent in a mile, or less, before reaching the single-log bridge across the true North Fork of the San Joaquin, is 1,600 feet; the rise thence to top of King Creek hill is 3,100 feet; then in a mile to ford of King creek, you descend 1,500 feet; and from the single-log bridge across the main San Joaquin to the highest point in the gap before you descend to Mammoth City is over 2,000 feet. These facts speak for themselves, as regards the wild and rough nature of the route. Yet it is entirely safe, and enjoyed with a zest by one who is well and can stand a little "roughing it." You observe that after reaching the greatest altitude on the route, 10,350 feet, the descent to Pine and Mammoth City is not great, the former being 9,850 feet, and the latter 9,700 feet—about their average heights. The best of pine, fir and tamarack timber is found at altitudes from 9,000 to 10,000 feet. Hence the great timber belt through here is about 40 miles wide.

A Road by This Route

Is much discussed, and is necessarily of greatest importance to Minaret, North Fork, Lake and adjacent mining districts. The first 20 miles to the neighborhood of Granite creek could be made with comparatively light work and cost, say, perhaps, \$25,000. Ten miles of road along Summit ridge, from North Fork district to Mammoth City, can be done, the miners say, with little labor and expense. This leaves about 20 miles of road where much heavy grading will be required, and where scarcely less than \$75,000 or \$100,000 in work and money will be needed. To Madera, Berenda, or Borden, on the S. P. R. R., such road would be about 100 miles, and would greatly diminish time and cost of freight from San Francisco. At present freight from San Francisco is usually sent to Mohave, Kern county, and thence hauled in wagons through Owens River valley by the Cerro Gordo Freighting Company, at \$5 per 100. Let the numerous fine mines now developing in that region prove as good as they promise, such road becomes a necessity and will be made.

J. W. A. W.

Fresno Co., July 20th.

Prospecting in Mono County.

EDITORS PRESS:—Not willing to lose an opportunity of informing the public on any mining interest, I present the following resume of a two weeks' prospecting tour in the vicinity of Bodie. Equipped with a pack animal and the proper implements I left Bodie in company with an old '49er, rather a rough customer, but a man whose experience in prospecting has been the very best. Our tramps were about 12 miles per day, and at the end of each day's travel camp was fixed, and the remainder of the day devoted to exploring the neighboring country and prospecting with pan for placer diggings and pick and shovel for ledge croppings. In favorable localities a day perhaps was spent in a single place. Our route lay southwest of Bodie and about Mono lake; in brief, we took the Sonora road to Mormon ranch, from thence to Dogtown and over to the old Mono diggings; then Mill creek was explored, and by coming around Mono lake the trip was finished. Throughout our course we met with mines, some producing a fair grade of ore and others rich ore, but with the lack of milling facilities, in this newly explored region, the work of opening up goes on slowly.

Half way between Mormon ranch and Dogtown the gold on the surface begins, and every swag in the nearly flat country, and every approach to a gulch, contains rich surface washings. Much of this land remains unclaimed because of the scarcity of water; however, I think, that with a small outlay, water could be brought from the creeks in the hills south in sufficient quantities to wash off the rich surface earth, and in any such work I feel sanguine that ledges would be encountered in the vicinity, because of the flatness of the country and the existence of a rich red quartz accompanying the gold. At Dogtown, 12 miles west of Bodie, there is much gold found on the surface running down to a depth of from 6 to 20 feet. Over the whole surface, in this vicinity, we find washings which pay from one-half to two cents to the pan, and in the gulches and creeks the value increases. The richest washings, which lie in Virginia creek, have all been worked once, and there now remains the tailings which are being worked over by Chinamen. Here again, for the extensive surface washings, we find that a small outlay would insure favorable returns were it not for one difficulty, viz.: The farmers above and below will not allow the water to be used for mining purposes, they claiming precedence in its ownership.

To proceed, we find no deep mining about Dogtown, though there must be important

[CONTINUED ON PAGE 102.]

MECHANICAL PROGRESS.

The New Edison Telephone.

The New York correspondent of the *Times* reports a recent private exhibition by Mr. Edison of his new electro-chemical telephone, of which during the last few months remarkable results have been predicted. About 30 or 40 journalists and friends of the inventor went over to his laboratory, where the exhibition was given by Mr. Edward H. Johnson, Edison's chief assistant. Mr. Johnston took first in his hand the receiver of the Bell telephone (the one now best known), and showed its capabilities. As is well understood, the voice transmitted by this telephone can be heard only by putting the receiver to the ear. He then exhibited the Bell telephone with the Edison transmitter, a carbon button, but the voice was still very faint, the articulation being audible only when assisted by the flaring funnel used in the phonograph. Then he turned to one of the odd-looking contrivances before referred to, which was fastened to the wall, and which looked like a coffee mill with a glass front, and, giving the signal to the sender, who was in a distant part of the grounds, he turned a little crank revolving in the edge of the coffee mill, and it shouted in a voice that startled the listeners, "Halloo! How are you? How do you get this?" The voice was so loud and strong that it might have been heard and distinctly understood 50 feet distant. Indeed, some members of the party went into the next room and still heard it saying,

"Now is the winter of our discontent
Made glorious summer by this sun of York."

and when the talker turned from familiar verses and read the latest news from a morning paper, and finally read a page of travels from an unknown book, every word was distinctly understood. Some whose ears were not familiar with the peculiar half-muffled, half-metallic voice of the telephone and phonograph missed some words, and some acquaintance with the instrument seems to be essential to a complete understanding of all its speech. This telephone contains no magnet (which has hitherto been regarded as essential), and that Mr. Edison has substituted for the magnet a carbon button transmitter at the end where the speaker stands, and a small revolving cylinder of chalk at the end where the hearer awaits the message. This spool of chalk is turned by the crank before mentioned, and its virtue seems to reside in the caustic soda with which the spool has been thoroughly saturated, which, Edison explains, must crystallize and polarize before becoming effective. On this spool rests a steel tongue, about as large as the wooden toothpick of commerce, free at one end, and at the other fastened in the center of a disc of mica, which it causes to give vocal vibrations like the mica disc in the phonograph. The visitors experimented with the new phonograph in every conceivable way, and the conclusion reached by all was that it is so much more powerful than any other phonograph as to lift it almost above rivalry. Experiment also showed that the voice is really magnified in transmission, and delivered in a louder tone than that employed by the speaker.

The Writing Telegraph.

Cowper's writing telegraph has been placed on the London and Southwestern railway, and it works most successfully, says the *Engineer*, from Woking to Waterloo, a distance of 26½ miles, writing off the messages in ink, one after the other, in a perfect legible manner, whether regular line messages or messages made up in order to give the instrument more work to do. On some days more resistance coils of wire have been introduced into the two line wires, in order to represent greater distances, and thus 62½ miles and 99½ miles have been worked through in a most satisfactory manner, it only being necessary in such cases to add a few more cells of the battery, which in no case was as powerful as is very often used on the same line. The effect of the currents through the multitude of other line wires, in close proximity to the two in use for the writing telegraph, was closely observed, and the effect of induction was so exceedingly small as only to produce occasionally a slight roughness in a straight line, when the pencil of the operator was quite stationary, but such effect was hardly ever perceptible in the writing itself, and never to affect its legibility.

The fact of this instrument requiring no clerk to receive the message, translate and write it down, seems to be much appreciated, as a half-dozen such instruments may be telegraphing their yards of messages into one office without the least assistance from the clerk, who may, from time to time, cut off and send out the ready written messages; so that not only is the time of "calling" (as with ordinary instruments) saved, but the time of waiting till the clerk can attend at the other end of the line to receive the signals, which very often amounts to a much longer interval than is required for the whole message to be transmitted, especially in offices fitted with many instruments.

There is also a great advantage in having an absolute record of what has been sent by the writing telegraph at the transmitting station.

Another very important feature is the facility with which all that it is necessary to learn to use the instrument may be found out in five minutes. Every operation is exceedingly simple, and there are practically no fine adjustments anywhere. Variation in the power of the battery is of no importance, as its effect may be overcome by simply pushing the levers, carrying the springs against which the needles pull a little further in or out, as may be necessary. The pen, which is a very small glass capillary siphon tube, is, though of glass, very strong—it may fall several feet on to a bare floor without breaking—and is very easily adjusted.

The Electrical Alarm Compass.

A short time since Mr. Henry A. Severn, of Herne Hill, England, brought out an ingenious compass alarm for use on shipboard. Its purpose is to make the compass signal automatically any considerable deviation of the ship from a desired course. Over the compass card are placed two index hands which can be adjusted to any angle; and these hands are so connected with an electric alarm that the moment the compass needle passes the limit of variation prescribed an alarm bell will ring in the captain's office, and continue ringing until the ship's proper course is restored. In this way any departure from the ship's course, as ordered by the officer in command, whether due to the steersman's inattention to duty or to a misunderstanding of the orders given, will be instantly made known. Of course when the officer gives his orders to the steersman he sets the index hands to correspond, and after that he is relieved of the necessity of constant observation of the compass to be sure that his order is strictly carried out.

This invention is just now receiving much attention in the scientific and other journals in England; and it is currently described as novel as well as likely to be useful. Its novelty, however, is open to question. In principle, and apparently in mechanical construction, it is substantially identical with the electro-magnet attachment to ship's compasses patented in this country by Alfred Foucault, July 19th, 1870.

The essential part of the claim for this patent was the construction and arrangement of a compass, so that, by reason of any material variation in the route of the vessel, the needle of the same would close an electrical or magnetic circuit and sound an alarm.—*Scientific American*.

RAISING COAL CORVES.—The essential feature of the invention of Mr. C. Jeanson, of Paris, is the use of endless chains passing over and under pulleys at the pit's mouth or other situation, and under a pulley at the bottom of the shaft, also in a guide fitted within the shaft for preventing the slip of the chain, should say, the up running portion be weighted out of proportion to that of the other or down running portion, or vice versa. The endless chain or chains carry at intervals a series of projections which take hold of the trucks, wagons, or corves when they are pushed along a line of rails in proximity to the lower pulley, in order that they may be lifted. The trucks in the shaft while being lifted pass between pulleys which guide the chain or chains; these passing through a break or equilibrium apparatus to prevent them slipping should they be unequally weighted. The equilibrium apparatus is composed of a framework between which are chain wheels having sprockets or teeth to engage with the links of the chains, and against which rollers press to keep them in contact. The apparatus is suspended in the shaft and is under the control of weighted levers, which produce an equilibrium or balancing of the loaded trucks with the empty ones. When the trucks arrive out of the pit or shaft they pass between an upper set of pulleys, and become deposited upon the ground or upon rails to enable them to be moved away as desired, each truck as deposited releasing itself automatically from its connection with the chains.

ROCK DRILLING BY ELECTRICITY.—The application of electricity for the purpose of drilling or boring rocks has been suggested by M. Gaston Plante, the inventor of a process of engraving on glass by the same agency, which was made known in 1877. In the latter process, one of the electrodes conducting an electric current of high tension, being brought in contact with the glass, in presence of saline solution, acts like a graver or diamond, by tracing grooves in the surface of the glass, and even digs into it quite deeply. In spite of its great hardness, rock crystal can also be attacked by the same method; and, if not engraved regularly, it at least cracks into small fragments, and is finally disintegrated. Under conditions analogous to these, the electric current might be substituted for diamonds in the operation of drilling rocks. M. Plante states that electrodes of platinum would not be necessary, for here it is not the metal of the electrode that is affected, but the silicious matter, in contact with a saline solution. Metallic points or projections, suitably located at the extremity of the drill, isolated on a part of its length, and actuated by a rotary movement, would lead the electric current to the surface of the rock to be pulverized, and would thus replace those numerous and expensive diamonds which are set in the head of the drills employed in the present system of rock-boring.

SCIENTIFIC PROGRESS.

Meteors and Meteoric Phenomena.

When observers band together to watch every quarter of the sky, and to keep on the lookout through the whole night, the number of meteors that present themselves is very great. In this way it has been ascertained that upward of 30 on the average, which are conspicuous enough to be seen without instruments, come within the view of the observers stationed at one locality. And it is computed that telescopic meteors must be about 40 to 50 times as numerous as those visible to the naked eye.

These results may be obtained from observations made at one station; but when concerted observations are carried on at different stations several other facts of interest come to light. By simultaneous observations at distant stations, it has been discovered that the light of meteors above the surface of the earth usually ranges from 120 down to 20 miles, the average height being about 60 miles; that the direction of their flight is toward the earth, either in a vertical or in a sloping direction; and that their speed in most cases lies between 30 and 50 miles a second.

We thus arrive at the conclusion that visible meteors are phenomena of our own atmosphere; and as the atmosphere reaches a height, at most, of 150 miles, and is, therefore, but a thin film over so vast a globe as the earth, it is obvious that the spectators at any one place can see only a very small portion of the meteors which dart about through all parts of this envelope. After making allowance for this, we are forced to conclude that no fewer than 300,000,000 of these bodies pass daily into the earth's atmosphere, of which about 7,500,000 are large enough to be seen with the naked eye on a clear night, and in the absence of the moon.—*Popular Science Monthly*.

WHERE DID MAN ORIGINATE?—The various writers and thinkers on the subject of pre-historic man generally concede that the races of to-day have radiated over the globe from some point in Asia. Indeed, the traditions of different nations lead to the conclusion that this point of dispersion was located in the high central regions of that country. There, apparently, the dog, horse and ox were first domesticated, and can at the present time be found in their natural, wild state. Hudson Tuttle says, in his "Arcana of Nature," that "man originated near the equator, where the climate was better adapted to his defenseless condition and food abundant." This conclusion seems to be based upon the impression that the different zones of the earth occupy the same relative positions now that they have always done, and can hardly hold good in view of recent developments. Colorado, an almost unexplored country, comparatively speaking, to the scientific world will be apt to change the logical reasonings that have so far been advanced upon this interesting subject. Senor Altamirano, of Mexico, the best Aztec scholar living, claims the proof is conclusive that the Aztecs did not come to Mexico from Asia, as has been long universally believed, but that they were a race originated in the unsubmerged parts of America, as old as the Asiatics themselves, and that that country may even have been peopled from this. From the ruins recently found, the most northern of any yet discovered, the indications of improved architecture, the work of different ages, can be traced in a continual chain to Mexico, where they culminate in massive and imposing structures, thus giving some proof by circumstantial evidence to Altamirano's reasoning. But now, as to the antiquity of American man as shown by the yet recent discoveries in Colorado.—*Popular Science Monthly*.

PHOTOGRAPHY IN COLORS.—Capt. Abney recently submitted to the Royal Society, London, some pictures of the solar spectrum on silver plates, and also on compounds of silver, held in place by collodion. The natural colors of the spectrum had imprinted themselves on the plates, those on the silver being more brilliant than those on the collodion, but the latter could be seen both by transmitted and reflected light. Without entering into details of the process by which he obtained the pictures, he stated in general terms that they were produced by the oxidation of silver compounds during two minutes' exposure with a wide slit. Many months ago, when Becquerel showed examples of natural colors, effected through the agency of light, Capt. Abney said that the probable explanation of the result was the oxidation of the silver compounds employed; and he is now confident that he was then correct, that the colors are not caused by interference. The coloring matter seems to be due to a mixture of two different sizes of molecules of the same chemical composition, one of which absorbs at the blue end and the other at the red end of the spectrum, and the sizes of these molecules are unalterable so long as they are exposed to the same wave lengths as those by which they were produced. He believes it possible and probable that the colors may be preserved unchanged when exposed to ordinary daylight.

MAGENTA DYE.—By permitting vanadium to act at 200° Centigrade, on a mixture of nitrobenzol and commercial aniline, or on a mixture of pure aniline and nitro-toluol, Schmidt and Baldensperger, of Mulhouse, claim that an excellent magenta can be produced in either case.

FOSSIL RHINOCEROS IN SIBERIA.—In a communication to *La Nature*, A. Hoffmann, of Moscow, announces the discovery, in Siberia, of the head of a rhinoceros (*Rhinoceros tichorhinus*), which still retains, in a wonderful state of preservation, nearly all its covering of flesh. "This head," he writes, "was found near a small stream, called the Balantai, a tributary of the Yany, at the distance of some 200 versts from the city of Vorshvianska. M. Gorokoff, to whom we are indebted for this discovery, made haste to communicate with the Imperial Geographical Society of St. Petersburg. A member of that Society, M. Tshersky, to whom the head was submitted for examination, says that it must have belonged to a young animal, for some of the teeth had not as yet quite come out from their alveoli. The entire head is covered with a strong tissue, hardened by time; but one side of it is badly injured. Here the flesh is in part decayed and crumbles away. A portion of the skull is bare, and we can see the dried muscles and veins; also, a portion of the spinal marrow, the latter having dropped out of the passage through the second cervical vertebra. This curious fossil head retains in perfect preservation the muzzle, the lips, the ears, the hair of half of the left side, a good part of the forehead, and on the right side of the upper portion of the neck, and several other parts. Further, we notice the places for two horns."

SPECIFIC GRAVITY BALANCE.—M. Gannal has recently devised a simple means of determining the specific gravity of liquids. With his densimeter hydrostatique all calculation is obviated, and the specific gravity is ascertained by simply reading the weight on the balance. The apparatus is made in the form of an olive, so that bubbles of air shall not attach themselves to its sides. The olive of glass or metal has a volume exactly equal to one decimal subdivision of a cubic meter. There are two different methods employed in the practical use of the apparatus. 1. We may suspend it on the platform of the balance, and after having produced an equilibrium, we plunge it into the liquid; the equilibrium is then destroyed by the loss of weight of the olive, and the number of grammes which it is necessary to add to the scale-pan to restore the equilibrium is the exact specific gravity of the liquid. 2. Or the liquid whose specific gravity we desire to ascertain may be put in a glass vessel on one pan of the balance; balance the scale-pan, and then suspend the olive in the liquid by means of a fine thread. The equilibrium is destroyed, and the scale descends on the side on which the olive is suspended, and the weight, which it is necessary to place in the other pan to restore the equilibrium, is equal to the specific gravity of the liquid.

STEEL FROM PHOSPHORIC PIG.—Mr. James Henderson, in a circular recently issued, calls attention to his patent, No. 106,365, dated Aug. 16th, 1870, for making steel from phosphoric pig, with the aid of fluorspar and iron ore, in an improved gas reverberatory furnace lined with lime or magnesite lime, so prepared that it can be put in as dust and harden rapidly under the action of a high heat, thus rendering repairs an easy matter. Mr. Henderson estimates the cost of reagents, coal and labor at \$2.14 per ton, on the basis of an output of 60 to 70 tons of steel in 24 hours, from a furnace costing \$4,000. The waste is replaced by the amount of metal reduced from the ore, while the value of the clay produced is considered equal to one-half the cost of the fluorspar, which reduces the figure given above to \$2 per ton. Early experiments made by Mr. Henderson, have taught him that the action of fluorine and oxygen remove the silicon, phosphorus and one half of the carbon in 15 to 20 minutes, while the remainder of the carbon is removed in from one to two hours by charging ore. He has found out also, that manganese may be alloyed with iron and steel by introducing oxide of manganese into his fluorepar mixture.

THE WORLD'S TELEGRAPH SYSTEM.—Leaving out the land lines, which connect all the civilized countries of the world with their neighbors, there are now over 70,000 miles of cable crossing the seas and oceans. New submarine telegraphs, rivaling in length the greatest now existing, are soon to be laid. A line from San Francisco to the Sandwich Islands, and thence to Japan—where now 5,000 miles of wire are in operation, though the first were only laid 10 years ago—so as to connect the island groups of the Pacific with the continents of Asia and America, will complete the telegraphic circuit of the globe. The king of the Sandwich Islands has granted a concession for the first part of this final link, and it will not be many years before we shall see it in working condition.

ANCIENT WISDOM.—The ancients knew the elements of science to a wonderful extent, and when Hippocrates declared that "*putrefactio autem supremus est gradus ad vitam*," he laid down a principle which moderne have with the microscope demonstrated to be correct. It would seem as if inspiration attended the investigations of the ancient sage, who, with in his own mind, developed theories which we moderns, with all our learning and progress, have not deemed proper to change.

COLORING FOR WINE.—Nessler has been thus far unable to ascertain when the coloring matters of mallows and hillyberries are used to color wine, and he considers it very probable that the natural red coloring of the grape does not differ essentially from these foreign substances.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

TELEPHUM MINE.—*Dispatch*, Aug. 6: The proprietors of the Telephum mine have made preparations for sinking the shaft 300 ft deeper. The holding works, just finished, are complete in every particular, having ample capacity for sinking 1,500 ft if necessary. The shaft at present is about 240 ft, at which point they have a ledge of good quartz, about 9 ft in width, and the indications are very favorable.

CONK MINE. Work has been recommenced on this mine. A 40-stamp mill is being erected. The company intend to give direct employment to about 250 men, most of whom will be underground miners. Four shafts will be sunk on the vein, and presented with the utmost speed and skill. The rock of this mine assays well, but the gold is so fine that the most improved mining apparatus is required to prevent a very large proportion of it from going to waste with the muddy water.

The lode is thin, and the vein has been lying idle for some time, will be started up again in a short time, to be thoroughly developed, by Eastern capitalists.

BUTTE.

BUENA VISTA.—*Mercury*, Aug. 8: A large ledge has been struck in this mine. Samples of the ore assayed \$250 per ton. The matter is decomposed quartz. Parties conversant with the property inform us that there are thousands of tons of the decomposed quartz, the ledge being one of the largest ever discovered in northern California.

CALAVERAS.

ITEMS.—*Citizen*, Aug. 6: Whittaker & Co. are engaged in prospecting their gravel claim in the vicinity of Vallecito and from what we learn will make it pay. Hans Christian, while working in his claim on Snake gulch in the vicinity of Vallecito last week, found a nugget of gold worth \$75. Martin's claim and John Arrata's claim are being worked, but with what result is not known, as they cannot clean up until water can be secured when the rains come.

EL DORADO.

GLENNVIEW.—*Democrat*, Aug. 9: At a depth of 60 ft this mine has a 74 inch ledge, with well-defined scale foot and hanging walls, and a beautiful soft "gouge" of fully six inches. The walls are as smooth as glass. The trend of the ledge is from the northwest to the southeast. Drifts have been run in both directions from the 60 level, which have established the fact that the "pay chute" has a length of at least 1100 ft. The ore in this chute will average at least \$35 per ton, and its location is very favorable for large extraction of ore at small expense.

INYO.

MONROE.—*Independent*, Aug. 9: South drift, 300-ft point, run 11 ft, drift from winze, 11 ft; 300 drift, 19 ft; crosscut from connection drift, 1000-ft point, 30 ft. Upraise from 311 ft, 100 ft, raised 16 ft. Total length of south drift, 300-ft point, 130 ft. Drift from winze, 54 ft; drift, 800-ft point, 94 ft; crosscut from connection drift, 75 ft. Total height of upraise, 1100 ft, point, 35 ft. Still carrying a fine face of ore in drift from winze, 300-ft point, have 100 tons of ore in sight at present, showing a good prospect for a continuance. The drift at 800-ft point is looking very favorable for ore at that time.

KERASOKE.—At about 300 ft from the mouth of the tunnel a winze is being sunk to further develop the extensive body of ore exposed in top and bottom, and for about 60 ft in length in the tunnel near that point. This ore body for about 20 ft in length, as shown in the roof of the tunnel, is from 12 to 25 inches in width. The tunnel at this point is about 500 ft from the surface. The country rock is granite, but for more than 100 ft the crosscut no granite is found at all; instead there are innumerable clay seams, with more or less quartz and streaks of paying ore besides the larger body above mentioned, interspersed in trap rock. It is evident that the ledge or ledge matter is not less than 100 ft in width. The pitch is about 30° westward into the mountain, and no hanging wall proper has yet been found. From a point a few feet back from the winze at the crosscut is being run directly in line for the Cliff mine.

MONO.

PRESCOTT DISTRICT.—*Bodie News*, Aug. 7: The ledges are well defined and the ore produced from them running high in silver. The presence of base metal is apparent in all portions of the country, and is freely interspersed with pyrites of iron throughout the rock. The ledges crop out boldly, and are well defined as to character; but the real merit of the district has yet to be tested by practical work in the mill or furnace.

MOJO.—A drift south on the last ore vein cut has been started. The ledge is 4 ft wide, developing very richly as progress is made south. The main shaft has attained a depth of 474 ft.

SOUTH BRYAN.—Work is being pushed ahead with vigor in the drifts on the 350 level, and the ledge is looking remarkably well. Winze No. 2 from this level has attained a depth of 40 ft, and the ledge in the bottom is 3 ft wide of good ore.

NORTH STANDARD.—Sinking and timbering the shaft is going on steadily, the bottom being still in the same favorable formation. Have cut through a small ledge about eight inches in width of good ore, assaying very high.

SMITH.—The north drift, 200 level, is now in 313 ft; progress since last report, 3 ft. The ledge is about 20 inches wide. The east crosscut from this drift has been extended since last report 12 ft; total length, 206 ft. The ground works better than heretofore. The north drift, 300 level, has been run during the week 18 ft; total length, 306 ft. The ledge is looking well, and is about 3 ft wide. The south drift, same level, is in 247 ft; progress for the week, 32 ft. The ledge is 3 ft wide.

SOUTH STANDARD.—The north drift from the 400 level is in 30 ft from the shaft, and the crosscut from the same 25 ft to the east. A vein 2½ ft in width was passed through in this drift of the same character as that followed in the drift from the shaft.

BROOKLYN CON.—The ledge is looking well. The west side and bottom of the shaft is in four ft of fine looking quartz, and no footwall has been reached as yet.

RED CLOUD CON.—The south drift on the Packard and Morton vein from this level is in 30 ft, and the north drift 15 ft. The ledge in both directions shows an improvement, the porphyry borders generally being better bodied than the ledge having disappeared, and decomposed quartz and clay taking their place. Fine prospects in coarse gold can be obtained anywhere in the face.

JUPITER.—The station for the 400 level has been finished, and crosscuts east and west commenced. Work will be at once resumed in the shaft. From the 250 level the winze on the Daly vein has attained a depth of 120 ft. The ledge in the bottom is 4 ft wide of good ore.

TIOGA.—The shaft is now 50 ft below the 520 station, and making good headway. The Syndicate drift is in 300 ft north of the shaft. The drifts north and south on vein No. 3 are still being extended, and the ledge maintains its usual width. The west crosscut on this level is going somewhat slowly on account of bad air. The winze on the Daly vein from the 320 level has attained a depth of 150 ft, the ledge continuing strong.

VORTEX.—The ledge in sinking continues about two ft in width of very good ore, showing spots of very rich quartz filled with free gold.

UNIVERSITY.—The shaft is now down 60 ft and well timbered the whole distance. In the bottom a ledge of fine looking quartz is running, which predominates largely in silver.

SOUTH NOONDAY.—The north drift is now in 30 ft from

the shaft, the vein being 2½ ft wide of very fair ore. The walls are well defined. The south drift is 27 ft long, in the face of which the ledge is three ft wide of good milling ore. In a short time the new shaft will be started at a point where the ledge will be cut at a depth of 300 ft from the surface.

BELVER.—The south drift, 350 level, is in 115 ft; progress since last report, 44 ft. The ledge is 2½ ft wide, and looking well. The winze on the Falcon ledge is down 18 ft, and the ledge is 3 ft wide, of very fine ore.

MCCLINTOCK.—The work of sinking the new shaft is making fair progress. The ledge in the bottom is 2½ ft in width. The winze in the old shaft is confined to crosscutting on the 500 level.

ITEMS.—*Mammoth City Herald*: We were shown some rock from Mammoth district which assays over \$8,000 a ton. News from Laurel district is of the most encouraging character. Superintendent John Gorman informs us that rich ore has been struck in the Ida May mine. Every day being worked shows a marked improvement each day. Lone Mountain district is situated about 100 miles southeast of Lake. Mr. Buchanan, who has just returned from there, reports having made five locations, the average assays of which were \$115 a lb, one going as high as \$288 a lb. A furnace will be erected in the course of two months.

STANDARD CON.—*Standard*, Aug. 11: The north drift from the east crosscut, 355 level (vertical shaft), is in 310 ft, without any noticeable change in the ledge. About three and one-half ft of ore is being taken out in running the drift. The ledge continues to look well in the stopes, varying from a 15 ft in width. The winze from the 350 level, incline shaft, is now 60 ft in depth, the ledge in the bottom being seven ft wide of good ore. The upraise on this ledge is 68 ft above the ledge; the ledge is eight ft wide and looks well. In the different stopes, all the ledges are looking well. That in the West Standard is 10 ft wide, of good ore. In the south drift, 550 level, the ledge is eight ft wide, of good ore. In the Gildea stopes the ledge is three and one-half ft wide of good milling ore.

NEVADA.

GREAT BLOOMFIELD.—*Nevada City Herald*, Aug. 6: J. C. Broderick, a few days since, reached the bedrock in his mining claims at Little Grass Valley, northwest from Columbia hill and four miles due west from the Dorbec mine. This land has been used for agricultural purposes since the first settlement of the county, until a year or two since, when Mr. Broderick commenced to prospect for gold. Upon reaching the bedrock he found the gravel about four ft thick, and prospecting from 40 cents to \$1.25 per pan.

WASHINGTON.—A Chinese company are working the bar opposite Watson, and are said to be making good wages. The whole bar has heretofore been drifted out by white men. Capt. Swain is driving a tunnel in the Bessie Miller quartz claim, working two shifts and making five or six ft per day. He expects to strike the lead in a few days.

DEER CREEK.—A crushing of 25 tons of ore from the Builders and New Constitution ledges (both owned by the same parties), situated on Deer creek, opposite Worrell's ranch, has just been made. It yielded \$15 per ton in gold and sulphurets. It is the second crushing from the ledges, the first having paid \$10.50 per ton, and shows that increased depth is adding to the quality of the ore.

MINERAL MINE.—At the Oriental Con., work on the new mill is progressing rapidly, and it will be ready to start up in about two weeks. It has been found necessary to discontinue work underground for a few days, on account of no room for ore. Prospects in the mine are very favorable, and as soon as the mill is running, a good record will be made.

ITEMS.—Thomas Brown, working on the Guscetti milk ranch in Willow valley, has struck a ledge from two to six inches thick, at a point a short distance north of the Tam ledge. The ore is said to be rich. The complete returns of the last crushing from the Live Yankee mine are just in. The ore yielded in free gold and sulphurets \$54 per ton. A miner recently took a crushing of 15 tons from a ledge that runs into Captain's ranch, and paid him \$40 a ton. He is now hauling another lot from the same place hauled to the mill, and it looks even better than the first. There is now between 30,000 and 40,000 tons of tailings on the Dorbec dump, and competent judges believe it will pay from \$1 to \$3 per ton if any plan can be secured to wash it clean.

BUREAU MINE.—The lead of this mine is of good size and prospects finely. Last summer a shaft was sunk 150 ft deep, and from the shaft a drift was run 35 ft to the lead, but the water being bad, a tunnel was commenced to drain the mine, and it is expected to reach the lead in a few weeks. The mine is of quartz and is situated on the south side of the South Yuba river, nearly opposite French corral.

ITEMS.—*Transcript*, Aug. 5: R. S. Osburn & Co., of Esplanade Gap, are putting up works on the Blackhawk ledge, eight miles southeast of Washington, with the intention of testing the Robinson process of reducing ores. There is a large quantity of surface ore on the dump, and operations will commence on it immediately. An ore body has been tapped on the Blackhawk ledge. The ledge on the Comanche lead averages two and one-half ft in thickness and has two chutes of pay ore. A tunnel has been started on the old Union ledge which is now 30 ft down. The Nevada County Con., Alpha, Omega and Great Washington companies have commenced a combination tunnel on a level with the bedrock in the Omega mining and water company's ground.

SAN BERNARDINO.

ITEMS.—A great deal of placer mining is now going on in the San Bernardino mountains, and much gold is being taken out in small quantities.

SANTA CLARA.

ITEMS.—James W. Corless, and several others, claim to have discovered a gold and silver-bearing ledge near the headwaters of Permanente creek, in the Santa Cruz range. Locations have been made on 7,500 ft, and the necessary papers filed.

SIERRA.

ITEMS.—*Messenger*, Aug. 6: Work in the Kenton mine, Sierra county, is progressing well. In upraise No. 1 from tunnel No. 2 is found a good grade of milling ore. There are large amounts of sulphurets that assay well, and they are being shipped. The mill is running steady night and day.

NEVADA.

WASHOE DISTRICT.

ALTA.—*Gold Hill News*, Aug. 14: Good headway is being made in sinking the incline, and the bottom is now 100 ft on the slope below the 1750 station. The only ore being extracted from the mine is in running on the incline from the 1450 to the 1350 level, and amounts to about 15 tons per day.

LADY BRYAN.—Running two drifts on the 750 level, one 20° east of south and the other 30° north of east, both starting from a point 150 ft north of the shaft. The north drift of the two is in the vein material containing quartz and low-grade ore in bunches. The south drift is in 100 ft from the shaft came to a body of clay running directly toward the Comstock. To the south of this clay country rock. A crosscut was started west from a point 50 ft north of this clay wall, which is now in porphyry and low-grade quartz.

MEXICAN.—The joint Ophir winze on the south line, 2100 level, is down 46 ft, and is making slow progress, on account of water. On the 2000 level the joint Union Con. winze on the north line has been sunk 124 ft. The joint Ophir west crosscut on the south line is now in 30 ft, and is in the same character of hard, blasting porphyry that shows on the east side of the Harby vein in the Ophir mine.

ORION.—The main incline is 150 ft below the 2300 station on the slope, the face in quartz. On the 2300 level the north drift is in 122 ft. Excavating for the tank and balance-bob stations progressing well. On the 2100 level

the joint Mexican winze on the north line has been sunk and timbered 46 ft. This work is making slow progress, on account of water. On the 2000 level the joint Mexican west crosscut is now 29 ft from the main north drift in hard, blasting porphyry. The work of extracting ore from the Harby vein continues, and the stopes are looking well.

STOK CON.—On the 1600 level the east drift to the Union shaft is in 118 ft from the main north drift. Work on the joint Mexican crosscut on the south line continues. A drill hole is being run due south into Union Con. ground from the Sierra Nevada 2300 incline station, which corresponds with the Union Con. 2400 level. The hole is being run to ascertain whether the ore body extends to the east in gold-south.

CALIFORNIA.—The joint Con. Virginia west drift on the 850 level has attained a total length of 552 ft, and is still passing through hard porphyry, with some water in the face. Work on the California winze, 1000 level, has been suspended for the present. The excavations for the pump foundations at the 1850 station of the C and C shaft have been completed. A pump is being placed at the 2150 level.

CON. VIRGINIA.—On the 850 level the joint California west drift has been extended 27 ft; total, 552 ft. On the 1050 level, opening up and retimbering the southwest drift is making good progress. The north drift from crosscut No. 1, 1950 level, is in 72 ft, and is still in soft vein matter, showing some ore. Total length of east crosscut, 1115 ft, the face in bird's-eye porphyry, showing some quartz.

JUSTICE.—The south drift on the 1550 level of the Alta (1050 level of the Justice) will reach the line to-day, and to-morrow will be taken up and carried on to open the 1650 level.

THOJAS.—The northeast drift, on the third level, which was through quartz and porphyry, has been stopped and a crosscut started west, which is in fine-looking ground. The west workings above the second level have been discontinued. The upraise from No. 2 stopes is cutting quartz and low-grade ore.

TAH.—Putting the plunger pumps into the incline. One is already in place and good progress is being made with the work. Connections with the rod and the V-bob are being made.

CON. IMPERIAL.—The north drift, 2000 level, is in 570 ft, and is nearing the joint Alpha winze. Connection will be made some time this week. The winze has been cleared of water and repairs on the 2400 level completed. Retimbering the burnt drift, 2135 level, is making good progress.

UNION SHAFT.—The shaft is down 92 ft below the Ophir 2000 level, on the 1000 level the west drift to connect with the Union Con. east drift is in 30 ft, and in very hard rock. The foundation pit for the large pumping engine will be finished this week.

LEVATHAN.—The south lateral drift on the 750 level is making a pretty fair showing at present in low-grade ore, nearly half the face being in quartz assaying from \$5 to \$12 a ton. The north lateral drift on the same level continues in hard ledge porphyry.

NEW YORK.—On the 1200 level a drift is being run north in the ledge and is following a likely-looking vein of low-grade ore.

ANDES.—The winze below the 400 level is down 50 ft, the bottom in fine, lively quartz. The crosscut east, 350 level, is looking better, there being quartz in the porphyry.

YELLOW JACKET.—The winze is 164 ft on the slope below the 2500 level. The southwest crosscut on the 2500 level is in 53 ft.

NAOARA.—On the 500 level the two lateral drifts, north and south, continue in a very favorable formation of quartz and vein porphyry. Water gives no trouble.

MR. HOOD & YAKOVLEV.—The drift on the 1400 level is now 450 ft in length, and has of late been encountering harder rock than formerly.

BELMONT DISTRICT.

BELMONT.—*Courier*, Aug. 2: The mine has greatly improved during the past week. A raise from the 300 level was made about 29 ft since last report, through fine ore. A drift has been started north from the raise to connect with long raise from the 500 level under this ore body, and when completed will commence stoping out the ore. The ore body south of shaft, above the 200 level, is looking splendid. They have a slope 20 ft long with pay ore from 20 to 30 inches in thickness. A raise is being run from 20 to 50 ft north of this ore body, which is showing six inches of good ore.

CONVICT DISTRICT.

ITEMS.—From the gold fields in Convict district we hear encouraging reports, says the *Mammoth Journal*. There are about 16 men at work. The deepest shaft is down about 18 ft. Sluices will be ready for business in two or three days. As far down as any company has yet gone, gold has been found.

INDIAN DISTRICT.

ITEMS.—The Car and Viceroy, of the Sultan Hill company, are looking very promising indeed. The shaft of the former is down 115 ft, sinking into a very rich body of ore, which assays \$171 per ton; the latter's shaft is down 138 ft, and has a vein 13 ft wide, the ore of which goes \$74 to the ton. The Calhoun, owned by Capt. Prescott and others, has a shaft 50 ft deep and ore that assays \$222 per ton. The Illinois mine, owned in this city, is also a very promising piece of property, with an eight-ft ledge of silver and copper glance ore. The Tower mine, owned by William M. Lent, John F. Boyd, and others, is down 200 ft in rich black sulphate ore. The owners have already taken out over \$100,000 from that mine.

PARADISE DISTRICT.

ITEMS.—*Silver State*, Aug. 7: Parties report great excitement at Willow point over a rich mine found on the east side of Paradise valley, about eight miles from Willow point. The discovery was made by George Hymer, and about 16 men at work. The deepest shaft is down about 18 ft. Sluices will be ready for business in two or three days. As far down as any company has yet gone, gold has been found.

ITEMS.—*Silver State*, Aug. 12: New mines have been discovered in the Paradise range of mountains. Three ledges have so far been discovered, one of which carries carbonate ore containing a high percentage of lead and from \$60 to \$100 per ton in silver. This lead has been opened several ft by a cut, and shows six or eight ft of ore. Another ledge shows three ft of ore, containing chloride ore which assays up to \$1,007 per ton in silver, while the third ledge is of unknown width and contains considerable white quartz and galena. These ledges were discovered not over a week ago and it is impossible to form a correct estimate of their value or extent.

PIOCHE DISTRICT.

ITEMS.—*Eureka Sentinel*, Aug. 7: Another valuable strike has been made in one of the Wyandotte company's mines at Tem Pahute. It is very rich chloride ore, and the indications are such that it will prove to be a very large body. This strike was made eight days ago. The body of ore is 16 ft wide and very rich. The ore is now being moved smoothly along. The working force in the mines has been considerably increased of late, and it is thought that the mill will be in thorough repair and the stamps crushing ore about the first of next month.

PRESCOTT DISTRICT.

ITEMS.—*Esmeralda Herald*, Aug. 2: The Rush mine, owned by Messrs. Hamilton, Watkins & Randolph, shows assays from \$106 to \$377 per ton. The ledge is about four ft wide and well defined. The Snowdrift is looking well. The Dome company is taking out plenty of good ore. The ledge has been tapped in the Webfoot at the depth of 40 ft, and they have run through about 10 ft of ore that assays well. The Bulger is a gold ledge, 10 ft of ore in gold but no silver. The camp contains about 150 men.

TIBO DISTRICT.

ITEMS.—*Eureka Sentinel*, Aug. 5: Charles Streiberger showed us the result of two assays of the Oliver Twist ore. The first-came went \$320.00, and the second-came \$42.40. The ore carried a few dollars in gold to the ton. The

[CONTINUED FROM PAGE 98.]

ledges not far distant. Following up Virginia creek we reach the Mono region. The work all about here can only be carried on five months in the year, the balance being so cold as to prevent progress.

About Mono diggings, the oldest in the country, there are found rich ledges of quartz, though generally of small size. When mined, the ore is worked by an arastra, which, according to the miners' belief, save more gold than a mill. Mono diggings at first created a great excitement, and many an acre of granite bedrock was laid bare in a short time. Soon, however, the great Aurora excitement came on, and the whole section was utterly deserted—tools, claims and cabins were left, and the interest has never since revived; partly because, in the absence of the miners, the water was all monopolized and put under a single head, now held to be sold by the inch at a high figure.

Contrary to the general opinion on the paragenesis of gold, we find in the upper Mono gulch, ledges of quartz well defined but small, with both foot and hanging wall of solid granite. How deep these ledges run is not known, they having been mined but 20 feet at present, but thus far the quantity and quality increases. The metal itself can be detected in about every third specimen, and all consists of free-milling ore. Yes, gold is where we find it, be it in granite or slate. There has been extensive prospecting done in Mono gulch, and as it continues, I think, with many others, that there are valuable ledges to be found, from which proceeded the placer gold which paid the early miners so well. Otherwise than the mining, there is nothing attractive about this region, it being a dry, desolate ground, sparsely clothed with sage brush and studded with great granite boulders which loom up 30 and sometimes 50 feet, often beautifully marked with bright colored masses.

South of Mono diggings we encounter Mill creek, on which are found a few "washes," where the ground pays for sluicing. Following up the creek to the mountains we came to the best prospecting region I saw while out. Here, the ore is base, rebellious because of the presence of sulphurets; but the ledges are large, well defined and, owing to the steepness of the mountains, they can be traced easily without digging. Much of the land is claimed, but more than half of the claims could be obtained for little or nothing, and by proper management, some very profitable investments could doubtless be made.

From here we took up our homeward march, and nothing further of interest occurred. Throughout our trip, we encountered many prospectors; some hopeful, others despondent, and from the general outlook I should judge that the country was being rapidly opened up. There surely are many valuable opportunities for men willing to take a moderate risk in a new country.

J. H. WHEELER.

STRYCHNINE.—In Ceylon and several districts of India grows a moderate sized tree, with thick and shining leaves, and a short, crooked stem. In the fruit season it is readily recognized by its rich, orange-colored berries, about as large as golden pippins—the favorite fruit of many birds—within which are the flat, round seeds, not an inch in diameter, ash-gray in color, and covered with very minute silky hairs. The Germans fancy that they can discover a resemblance in them to crows' eyes, but the likeness to them is purely imaginary. The tree is the *strychnos nux vomica*, and the seed is the deadly poison nut. The latter was used as a medicine by the Hindoos, and its nature and properties were understood by Oriental doctors long before it was known to foreign nations. Dog-killer and fish-scale are two of its Arabic names. It is stated that at present the natives of Hindostan often take it for many months continuously, in much the same way as an opium eater eats opium. They commence with taking the eighth part of a nut a day, and gradually increase their allowance to an entire nut, which would be about 20 grains. If they eat it before or after food, no unpleasant effects are produced, but if they neglect these precautions, spasms are produced.

DIVERTING THE OXUS RIVER FROM ITS PRESENT COURSE.—One of the numerous engineering problems which it has been left to this generation to solve, is the turning back, by Russian engineers, of the Oxus into its Caspian Sea channel, from which it was diverted into Lake Aral by Octai Khan, when besieging Khiva in 1235. Immediately after the Khiva expedition of 1873, a scientific survey was made of the Lower Oxus, and most of the experts were of opinion that the progressive diminution of the river by artificial irrigation, and the evaporation consequent upon the destruction of the forests which shielded it from the sun, had made its volume insufficient to traverse an extra distance of nearly 5,000 miles encumbered with deep sand. It is now stated, however, that the experiment is actually being made; and the Lower Syr-Daria being only 12 inches deep in summer, the Russians may well do their utmost for the Oxus, as their only possible waterway into the heart of Central Asia.

A BUFFALO paper says that nearly the entire right of way for an oil pipe line from the Bradford oil district to that city has been secured, and is led to infer that nearly all the desired capital has been subscribed. The surveys it says have already been quietly made.

Notes on the Fishes of the Pacific Coast.—No. 2.

Scorpius californiensis, Steindachner.—This is another of those species which only occur in our markets on rare occasions. The individuals described by Dr. Steindachner, were collected at San Diego, and, as a very large proportion of the fish fauna of that locality is different from that of San Francisco, it was with a great deal of interest and a little surprise that I found, upon comparison of the single specimen of this little fish with Dr. Steindachner's description of *Scorpius californiensis*, that they agreed in every particular. The example mentioned, now in our museum, came from Tomales bay, in a box of Embiotocidae or viviparous perch, and the dealer who saved it for me stated that he sometimes received two or three in a similar way from the same locality. I have since procured a larger specimen.

Scorpius californiensis belongs to the family of *Squamipennes*, so named from the growth of scales upon the surfaces of the vertical fins. All *Squamipennes* are high, thin fishes, with ctenoid scales; and a single dorsal having the spinous portion well developed.

Only two species of the family have been described from this coast, and one of these, *Ephippis zonatus*, Girard, I have not yet seen.

The fish now in our collection is 7.6 inches in total length, and 2½ inches in greatest depth of body; but the species attains a length of 10 or 11 inches.

It may be recognized at once, by its bluish gray color; rather small ctenoid scales; small mouth with an even row of comparatively large teeth, backed by several rows of smaller teeth, and by the covering of small scales which invests all the soft rays of the dorsal and anal, the caudal, and much of the exterior of the pectoral and ventral fins.

Porichthys porosissimus, Silver-spangled toad-fish; *Porichthys notatus*, Girard.—The name here given to this fish embodies one of its most noticeable peculiarities, namely, the rows of pores upon the lower parts of the body, each shining like a silver spangle. It can scarcely be entitled a food fish, yet it is eaten in considerable numbers by the Chinese, and is occasionally brought to market. The ugly head, dark-colored scaleless body, and altogether bizarre appearance of this fish are probably the principal reason for its rejection by white people. Doubtless the Chinese are as good judges of fish as we are, but their ideas of beauty possibly differ.

In the month of June, or thereabouts, this fish comes to the shore, and fixes its residence under rocks, to the lower side of which it attaches its ova, which are as large as a pea. In this position I once found numerous examples in Tomales bay, and was at first much surprised to find myself greeted, when I endeavored to pick them up, not only with a dig from the sharp spines upon the gill covers, but with a most emphatic grunt of dissatisfaction.

This fish must therefore be added to the number of those which produce sounds. It attains a length of about 16 inches.

Ophidium Taylori.—The first mention of this fish may be found in the Pac. Rail. Rep., vol. X., p. 133, where Girard gives a few of its specific characters, and states that it inhabits the sands of Monterey beach.

During the months of March and April a few individuals have on several occasions been brought to the markets of San Francisco, and inquiry elicited the information that they were found at Bolinas bay, to the north of San Francisco, and that they lived among the sands and rocks. Some of those obtained came from Monterey or its neighborhood.

Ophidium Taylori is a long, eel-like fish, with the dorsal and anal fins formed entirely of soft rays and continuous with the caudal; the pectoral fins placed in the lower half of the height of the body; the ventrals represented by two long bifid filaments placed far forwards on the under side of the bone of the tongue; the mouth rather small, and the teeth of small size upon the jaws, vomer and palatines. It is the only known representative on this coast of the Ophidiidae, as restricted by Gill, a family characterized by gill-membranes continuous beneath the throat, continuous dorsal, anal and caudal fins, and an anguilliform, or eel-like body.

The other characters given above are common to all species of the genus *Ophidium*, but there are other peculiarities which distinguish this fish from other known species. These are supplied by the arrangement of the teeth, the proportions of various parts to each other, the coloration and the structure of the air-bladder. In color, it is light olivaceous above, fading out on the sides into the whitish of the under parts. Along the sides are several rows of roundish, dark spots, the two or three uppermost continued almost or quite the length of the body, but most of them dying out in the pectoral region. The head has similar spots.

The air-bladder, or swim-bladder, is a comparative large ovate organ, ending posteriorly in a narrower fleshy portion, pierced by a small aperture, and having in front two saucer-shaped bony plates attached to the second vertebra. In the center of the external convex face of each of these a muscle is inserted, probably for the purpose of drawing forward the front of the air-bladder. Although this fish is not sufficiently common to be of much value as an article of food, it is excellent eating. It has no popular name.

Leurynnis paucidens, nov. gen. and sp.—As I find no mention of this fish in the works of

Gunther, Gill or Steindachner, I presume that it is new, although it is just possible that some naturalist with whose writings I am unacquainted may have described it. It belongs to the small family *Lycoptidae*, and, in common with most of its relations, has an elongate eel-like body, small scales; continuous vertical fins (that is, the dorsal, anal and caudal united) composed of soft rays, and contracted branchial apertures, the gill-membrane not uniting under the throat, but attached to a broad intervening space or isthmus. The genus *Leurynnis* is further characterized by the absence of teeth upon the palatines or vomer; the presence of small ventrals placed in advance of the pectorals; and the insertion of the pectorals in the lower half of the height of the body. The head is large and both deeper and thicker than any part of the body; the jaws very long; the teeth small and slender, in a single row except in the front of the mandible, where there are three or four rows; and the color olivaceous, the scales lighter than the skin, and the vertical fins margined with black. During the months intervening between September and the middle of March this species certainly did not occur in our markets, but from the latter date to May it occurred tolerably often, but seldom in sufficient abundance to make it of any account as an article of food, a circumstance which is to be regretted, as it is of excellent flavor, superior, in my opinion at least, to many of the flat fishes. The largest specimen I have yet seen measured only 10½ inches in length, and I presume that it does not attain much larger dimensions. The Lycoptoid fishes have considerable resemblance in general appearance to the Blennies, but may at once be distinguished from them by the absence of spines in the dorsal fin. This is the only species of the family found on our coast.

Quassilabia (1) cypho.—I give this name, provisionally, to a very singular member of the family *Catostomidae* or fresh-water Suckers. The only specimen I have seen was brought from the Colorado river, at the junction of the Gila, and was brought to the California Academy of Sciences some two years ago. Its chief external peculiarity, or at least that which is most likely to be noticed by an ordinary observer, is the singular hump upon the back, between the head and the dorsal fin. This hump is not a mere development of fat, as is the case with the less abruptly-rising humps of some kinds of fishes whose backs become more elevated with age, but is supported by a system of greatly-developed interspinous bones, the first of which is very large and strong, formed of a thick central pillar with a broad lamina in front and a broader behind. The under surface of the central pillar has a double articulating surface for attachment to the first vertebra. There are also other peculiarities in the structure of the anterior portion of the vertebral column. Another external character of importance is the structure of the lips. In the family generally the mouth is upon the under surface of the head, and is furnished with thick papillose lips, one upper or anterior; the other lower, or posterior. In one species, the *Quassilabia lacera* of Jordan and Brayton, known also as the Hare-lip and Split-mouth Sucker, the lower lip is small, and divided into two quite distinct lobes, while the border of the under jaw is cased with a rather hard, horny plate. These characters are also possessed by the fish under review, which may perhaps be considered as the Western representation of the Hare-lip Sucker of the rivers of the Eastern States. It differs, however, from that species in the considerable development of the operculum or gill-cover, which in *Q. lacera* is very small, as well as in the skeletal peculiarities above mentioned, so that probably a new genus must be created for it. Shortly after this example was presented, I read before this academy a few notes upon it, but they have been mislaid, and I now bring this species again into notice, partly because I have written a full description of it for publication in the Eastern States, where scientific research is considered of more importance than it is here; but chiefly in order to have an opportunity to ask any individual who may pay a visit to its habitat to bring us, if possible, a few more specimens.

Sphyrna malleus (the Hammer-head Shark).—A large species of Hammer-head Shark is found along the coast of Lower California, and presents characters in many respects similar to the *Sphyrna (Zygena) malleus* of Shaw, combined with others which approach *Sphyrna tudes*, Cuv. A specimen six feet one and five-eighths inches long is in this museum, to which it was presented recently by Messrs. Fisher and Chapman, while a much larger individual, apparently about 14 feet long, is in the Zoographical building at Woodward's gardens. The long hammer-like lobes into which the front part of the head is laterally prolonged are nearly one-third longer than their width at the extremity where the eye is situated; and the nostrils, which are in the front of the lobes, close to the eyes, have (in our specimen) a groove running from each of them along about half the distance to the center line of the head. The front margin of the head is sinuous, but not curved. In *Sphyrna malleus* the lobes of the head are normally shorter than in our fish, and the groove from the nostrils is longer, running along nearly the whole of the front part of the head. In *Sphyrna tudes* the front of the head is much curved, yet the ends of the lobes are distinct from the front; and the grooves from the nostrils run along more than the half of the front of the head. You will thus see that our hammer-head differs from either, yet I do not venture to call it a distinct species; for the con-

trary, I have reason to doubt whether one of the characters usually considered specific and constant, namely, the length of the groove from the nostrils, is to be depended upon. The large individual at Woodward's gardens has these grooves very short indeed, not extending one-fourth of the distance from the nostril to the center of the head. Now, as our specimen and Woodward's were caught near the same place (Mazatlan); as they are alike in the teeth, the fins, the outline of the head and of its lobes; yet differ in the nasal groove, I submit that the shortness of the grooves is the effect of age, and that this character is therefore not specific. The individual in Woodward's garden is the largest hammer-head I have ever seen in a museum, and I much regret that I was not allowed the opportunity of taking correct measurements of it.

Note.—Full descriptions of *Ophidium Taylori*, *Leurynnis paucidens*, *Chitonetus megacephalus*, and the new *Catostomid* will appear in Prof. Jordan's "Ichthyology of the United States."

A "Review of the Plenonecticidae of the Pacific Coast," containing full descriptions of all the species, new and old, known to occur on the Pacific coast of the United States, was forwarded to the Smithsonian Institution about two months ago for publication in the "Proceedings of the United States National Museum." The proof of this "Review" has already been revised.

[Concluded.]

Silver Mining in Chihuahua, Mexico.

For centuries Chihuahua has ranked among the most famous of the Mexican States for the production of silver; but from various causes, until very recently, the energies of Americans have not been directed to that rich region.

But thanks to American enterprise, that land is destined soon to pour into the United States the wealth which a century ago, glutted the avarice of the haughty Spaniard.

There are now in the State of Chihuahua at work, and organized for work, no less than six American companies, owning and controlling the richest and best of the mining property in the State. A brief mention of these is all that will be attempted at this time. The Santa Eulalia mining company owns the mines of Santa Eulalia, 16 miles from the city of Chihuahua.

Under the rule of Spain, these mines paid to the Catholic church a tax on \$111,000,000.

They are, without doubt, the most extensive deposit mines in the world. But for want of capital, they are still being worked by the ancient methods of the Mexicans. The company proposes to tunnel the mountain, build a railroad 12 miles to the forks of the Sacramento and Chihuahua rivers, and there establish large works for the reduction of the ores by methods. The Cusiquiriachic mines were purchased last fall by a company from San Francisco for the comparatively trifling sum of \$500,000. These mines are 90 miles southwest from the city of Chihuahua. The records do not show their former wealth, but it is known to have been great. The veins are true fissures, containing at the depth of 600 feet solid metal, in some places 15 feet wide, averaging nearly \$100 per ton. The ores are now being reduced by the lixiviation process with excellent results. The Batopilas mines, in the southwest part of the State, owned and operated by Wells, Fargo & Co., contain large deposits of native silver, and are enriching their owners. The records show that under Spanish rule these mines produced \$400,000,000. The consolidated mines of Parral, owned by the Knotts company of Chicago, are situated in the city of Hidalgo or Parral. The records show that these mines have produced \$60,000,000. They are true fissure veins, aggregating in length three-fourths of a mile, with a width of from 6 to 30 feet. The last six years working by the Mexicans yielded over \$900,000, the ore averaging \$81 per ton.

These mines have only been worked to a depth of a little more than 400 feet.

They own, in connection with these mines, at least 500,000 tons of cast-away ore, which average \$20 per ton, much of it yielding \$70 per ton.

For want of capital, these mines are still worked by the ancient methods of the Mexicans. But the company now has at the mines a large amount of modern machinery, and expects to secure sufficient capital to set it up and operate it on a large scale.

This company claims that it owns a larger body of good paying ore than any other one company in the world.

The Dry Mountain silver mining company, of Terre Haute, Ind., owns the mine La Luz, five miles west of Parral. This is one of the best mines in the district around Parral. It is a true fissure vein, as wide as nine feet, yielding from \$20 to \$100. For want of capital, this mine is also now worked only in the Mexican way. But the company propose to secure a good water-power which is accessible to them, and establish large works for the reduction of the ores. This company having no water to contend with, the cost of mining will be comparatively small. The Hidalgo mining and power company, of Chicago, owns the mine Las Gijas, in the Dry mountain, five miles west of Parral, which is celebrated for having at one time produced a large pocket of native silver.

This company propose to establish works for the reduction of the cast-away ores of the Knotts company, and do a general custom business, also establish a foundry and machine shop in Parral.—*Real Estate and Mining Review*.

THE ENGINEER.

SPEED OF RAILWAY TRAVELING.—The various German governments and others, who are interested in the problems connected with railway development which are pressing for solution in Germany, have been collecting information on all points bearing on the subject. Among other things, a paper has been published showing the different rates of velocity at which railway trains travel in different countries. According to this table, the swiftest runs are in England, between London and Dover, London and York, London and Hastings, where the average reaches 80 kilometers (50 miles) an hour. In Belgium some trains travel as fast as 67 kilometers (nearly 42 miles). The express trains from Paris to Bordeaux, Orleans line, averages 63 kilometers (39½ miles); the same speed is attained by the express trains between Berlin and Cologne. Between Bologna and Brindisi the average maximum is 50 kilometers (nearly 31½ miles). The average Austrian express speed is from 40 to 48 kilometers (25 to 30 miles). On the Moscow and St. Petersburg line one travels at the rate of 43 kilometers (nearly 27 miles) per hour; the same speed is observed in Switzerland between Geneva and Lausanne, and between Zurich and Romanshorn. But on the other Swiss lines one must be content with a slower pace. Thus, from Zurich to Basel the highest speed is 38 kilometers, and between Basel and Borne 34—say, between Solcure and Burgdorf the moderate gait of 25 kilometers, or a little more than 15½ miles an hour, is observed. There are in Switzerland no purely "through" trains which do not stop at intervening stations.

THE DRAINING OF LAKE FUCINO.—One of the greatest engineering undertakings of the present century, well fitted to rank with many attempted in Holland, not even excepting the projected draining of the Zuyder Zee, is the successful accomplishment of works by which the Appennine lake has become a thing of the past, and some 35,000 acres of the richest land recovered for cultivation. The labor of making the tunnel necessary for the task, and other works, has occupied nearly a quarter of a century, and Prince Torlonia has expended on the work more than ten millions of dollars. All the water has disappeared, except a small basin used to drain the surrounding district. The greatest length of the lake was formerly some 10 miles, and its breadth about seven, while the towns of Avezzano and Pescina are no longer in danger from the sudden rising of the water in this volcanic district. The idea of draining it is not a new one, and the remains of the aqueduct constructed under the reign of the Emperor Claudius were formerly shown to the traveler. This has been made use of in the present undertaking, and after the lapse of so many centuries the people of this Appennine district, some 2,200 feet above the level of the sea, are rejoicing over the completed work. Upon visiting the spot a few years hence it will be difficult to realize that those vine-clad hills were covered with water within so brief a period.

AFRICAN RAILWAY PROJECT.—The project of carrying civilization into Africa seems to be gaining ground in the minds of Frenchmen. An interesting report is published in the *Journal Officiel* by M. de Freycinet, Minister of Public Works. It is addressed to the President of the Republic, and urges the necessity of appointing a commission to examine the question in all its details, and report as to the practical possibility of uniting Algeria and Senegal to Soudan by means of a railway. The Minister of Public Works points out that many of the regions of Central Africa are by no means so sterile as they have been represented to be. The Soudan is traversed by the Niger, a great river, the banks of which are studded with villages. The population of this province is estimated by some travelers at over a hundred thousand inhabitants. The soil resembles in many parts that of Europe, and all the elements necessary for foreign commerce appear to exist in a high degree. This region can be got at on either side by Algeria and Senegal, and the idea of uniting Africa to the Niger by a railway upwards of 2,000 kilometers in length, although a bold one, is by no means a chimerical conception.

CANAL COMMUNICATION BETWEEN THE CASPIAN AND EUXINE.—In a recent issue of the Russian journal of the Ministry of Public Works, the project is discussed of a connection of the Caspian and Black seas by a system of canals, according to the designs of M. Daniloff, an eminent engineer. The proposed water-courses are to comprise a canal of 300 versts in length from the River Terek to the watershed of the Manitch, which links the Don with the Caspian; a canal of 320 versts from the mouth of the Katavs to enter the Volga near Astrachan; a third of 350 versts from the mouth of Katavs westwards through the valley of the Manitch to the Don; and finally, a branch from the canal to Serebriakoff on the Caspian. By means of another special branch to the Black sea, in the direction of the westerly portion of the Manitch, M. Daniloff proposes to provide a complete water thoroughfare between the Volga and the Don, the Black and Caspian seas.

USEFUL INFORMATION.

JOINING WIRE.—An improved method of joining fencing and other wire has been contrived by Mr. J. H. Nettleford, of Birmingham, by which a very secure junction is made, and the wire may be so prepared before it is supplied to commerce that the joining can be effected without the use of tools. The following is the manner in which the ends of the wire to be joined are prepared: Two or three inches of the end portion of the wire are first folded or doubled upon itself, this being effected round a peg or mandrel. A nearly elliptical hoop of about four times the diameter of the wire is thus formed, the extreme end of the folded portion of the wire being parallel with the straight portion of the wire, and separated therefrom by a distance equal to the diameter of the wire. The elliptical loop is bent into a plane, making a very obtuse angle with the parallel portions of the wire. In connecting together two ends of wire bent as described, they are brought together in such relative positions that the straight portions of the two wires lie parallel upon one another, each wire passing through the loop of the other wire. The parallel parts terminating the loops also lie parallel upon one another. By tightening the wires, the extreme end of each wire enters the loop of the other wire as the loops slide upon one another, and there is thus formed a junction somewhat resembling a sailor's knot, the parallel portions adjoining the loop of each wire being situated in the loop of the other wire. The junction thus formed is exceedingly strong, and the tighter the wires are stretched the more secure the junction becomes. This method of effecting a junction has the further advantage that the two portions of wire joined are in one of the same straight line. The loops at each of the ends to be joined are, by preference, made on the same side of the wire; they may, however, be made on opposite sides with nearly the same effect. In the latter case the two portions of the wire are not quite in the same line. Besides being applicable to the joining of fencing wire, the method we have described is also applicable to the joining of wires for various purposes, such, for example, as signal wires and telegraph wires.

HOW TO PRINT SEVERAL COPIES OF A LETTER. A new process, by M. Chardon, is as follows: Make a zinc tray about a quarter of an inch in depth, and pour into it a warm solution made as follows: Water, four ounces; sulphate of baryta, two and one-half ounces; sugar, one ounce; gelatine, one ounce; glycerine, six ounces. Write whatever is required to be printed upon a sheet of white paper, using instead of ordinary ink the aniline color known as "violet of methylaniline." As soon as the writing is pretty dry, lay it upon the gelatine surface and rub the back of the paper with the palm of the hand. The ink will be absorbed by the gelatinous product. All that is to be done in order to obtain a *fac simile* of the writing is to lay a sheet of paper upon the writing on the gelatine and rub the back with the hand. From 40 to 50 can thus be drawn off in a few minutes. We find that in warm weather, plates thus prepared remain too soft and adhesive to work satisfactorily. Better results are obtained when a larger proportion of barium sulphate—say three and one-half instead of two and one-half ounces—are used and the mixture is heated for an hour on the water-bath.—*Scientific American*.

PRACTICAL HINTS.—There is this difference between a plumb line and a perpendicular line. The former is always a vertical line; while the latter is one at right angles to some other line or surface, and may be either vertical or horizontal, or at any angle with either. A knowledge of geometry is very essential to becoming a good mechanical draftsman. In making the scorification assays of gold and silver ores, the powdered ore if mixed and covered with about ten times its weight of pure granulated lead in a small dish of refractory clay (scorifier), and introduced into the muffle of a cupellation furnace. If the ore is at all basic a few fragments of anhydrous borax (borax glass) are added to the contents of the scorifier. As soon as the lead has melted the door of the muffle is opened and the scorification proceeds until the ring of slag closes over the lead button. The scorifier is then removed and poured into a smoked iron mold. If, after breaking away the slag, the button is found to be small enough, it is immediately cupelled; if not it must be returned to the scorifier and reduced in size by scorification. The cupellation is the same as with the crucible beads.

THE MANUFACTURE OF DAMASCUS STEEL.—In a series of articles on mining and metallurgy at the Paris exhibition is promulgated the following interesting data on the method of making Damascus steel sword blades at Zlatoust, in the Ural. The pig iron used in making the latter is a spiegel, 8% of manganese, which is partly converted into puddled steel and partly refined. The cast-steel ingots of about five pounds weight are made from selected qualities of puddled steel, 61% of the crucible charge being hard, 23% medium steel, 10.37% refined pig iron, and 3.71% pure magnetic ore. The tilted bars are twice piled for shear steel, a layer of sulphide of antimony being placed between the different bars. The final pile is made of four square bars, about one-eighth of an inch in the side.

TO REMOVE FUSIL OIL FROM SPIRITS.—According to the *Brenneri Zeitung*, a single agitation of spirit with the following compound will completely remove the fusil oil from potato brandy, and will leave the fluid perfectly clear: Sugar of milk, part 1; starch powder, parts 2; powdered albumen, parts 5. About 4 ounces of the powder is sufficient for a gallon of spirits. Another journal gives the following directions for a similar process: "The liquid is sweetened with crushed sugar and strained, and one ounce of pure starch, half an ounce of finely powdered prepared albumen, and half an ounce of milk-sugar are added to every two gallons. The whole is well shaken several times and then allowed to rest for 24 hours. It will now be found to be beautifully cleared without filtration."

COMPOSITION OF EXPLOSIVES.—A German chemical journal gives the following analysis of explosives used as substitutes for gunpowder: *Diacetone*: Nitrate of potash, 50%; nitrate of soda, 25%; sulphur, 12%; sawdust from hard wood, 13%. *Acetone*: Chile saltpeter, 69.05%; carbon, 15.23%; sulphur, 11.43%; petroleum, 4.29%. *Petralite*: Nitrate of potash, 64%; impregnated wood or charcoal, 30%; autimonium crudum, 6%. *Johnite*: Saltpeter, 75%; sulphur, 10%; lignite, 10%; picrate of soda, 3%; chlorate of potash, 2%. *Carboacetone*: Nitrate of potash, 61.04%; sulphate of iron, 0.73%; soot, 24.65%; sulphur, 13.58%.

TO REMOVE RUST FROM STEEL.—Steel which has rusted can be cleaned by brushing with a paste composed of one-half ounce cyanide potassium, one-half ounce castile soap, one ounce whiting, and water sufficient to form a paste. The steel should first be washed with a solution of one-half ounce cyanide potassium in two ounces water. To preserve steel from rusting, a good method is to paint it with melted caoutchouc, to which some oil has been added. The caoutchouc must be melted in a close vessel to prevent its burning, and should be frequently stirred. It is also said that dipping the steel in a solution of common soda (about one in four) will preserve it from rusting.

FIREPROOF PAPER.—Fireproof paper may be made, according to the *Pharmaceutische Zeitung*, from a pulp consisting of one part of vegetable fiber, two parts of asbestos, 1-10 part of borax, 1-5 part of alum. The ink is made from 85 parts of graphite, 0.8 part of copal varnish, 7.5 parts of copperas, 30 parts tincture of nutgalls, and a sufficient quantity of indigo carmine.

POLISH FOR WALNUT WOOD.—Mix with two parts of good alcoholic shellac varnish one part of boiled linseed oil, shake well, and apply with a pad formed of woolen cloth. Rub the furniture briskly with a little of the mixture until the polish appears. This is probably as good as the more complicated polishes.

GOOD HEALTH.

Nerve Stimulants.

Dr. Brunton has the following interesting and suggestive remarks on this subject in a recent article in the *Contemporary Review*: "There are two nerves, known as the 'fifth pair,' which are distributed to the skin of the head and to the mucous membrane of the eyes, nose and mouth. These nerves are closely connected with the heart and vessels, and by stimulating their branches the circulation may be greatly influenced, as in the case of fainting. It is a curious fact that people of all nations are accustomed, when in any difficulty, to stimulate one or another branch of the fifth nerve, and quicken their mental processes. Thus, some persons, when puzzled, scratch their heads, others rub their foreheads, and others stroke or pull their beards, thus stimulating the occipital, frontal or mental branches of these nerves. Many Germans, when thinking, have a habit of striking their fingers against their noses, and thus stimulating the nasal cutaneous branches; while in other countries some people stimulate the branches distributed to the mucous membrane of the nose by taking snuff. The late Lord Derby, when translating Homer, was accustomed to eat brandied cherries. One man will eat figs while composing a leading article; another will suck chocolate creams; others will smoke cigarettes; and others sip brandy and water. By these means they stimulate the lingual and buccal branches of the fifth nerve, and thus reflexly excite their brains. Alcohol appears to excite the circulation through the brain reflexly from the mouth, and to stimulate the heart reflexly from the stomach, even before it is absorbed into the blood. Shortly after it has been swallowed, however, it is absorbed from the stomach, and passes with the blood to the heart, to the brain, and to the other parts of the nervous system, upon which it then begins to act directly. Under its influence the heart beats more quickly, the blood circulates more freely, and thus the functional power of the various organs in the body is increased, so that the brain may think more rapidly, the muscles act more powerfully, and the stomach digest more easily. But with this exception the effect of alcohol upon the nervous system may be described as one of progressive paralysis. The higher centers suffer first, and the judgment is the

first quality to be impaired, and this becomes the more so as the effect of alcohol progresses, although the other faculties of the mind may remain not only undiminished by the direct action of the alcohol on the brain, but greatly increased by general excitement of the circulation. By and by, however, the other parts of the nervous system are successively weakened, the legs fail, and the person falls insensible. It is evident, then, that only the first stages of alcoholic action are at all beneficial, the later stages being as clearly injurious.

NOURISHMENT IN TYPHOID FEVER.—UNSOUND LOGIC.—Dr. Samuel Peters (*N. Y. Medical Record*), in a paper on typhoid fever, refers to the importance of supporting the strength by nutriment, and adds: "I once had a case, a lady of large frame and plenty of adipose tissue, who drank every day four quarts, by measure, of pure milk. I was frequently inquired of as to the probability of her recovery. I answered that she *could not die*, because she was able to appropriate so much nourishment. She recovered," etc. Now it so happened that the present writer also had a case of typhoid fever, a young lady of good constitution, who was able to relish and appropriate an ample quantity of the same nourishment, and who died notwithstanding. No serious symptoms occurred during the first two weeks, and no active medication was required or employed. In the third week nervous and cerebral disturbances set in, with the result mentioned. Therefore, a patient *can die* in typhoid fever, even when well nourished. Dr. Peters is not the only medical writer who has made hasty and illogical conclusions.—*Pacific Medical and Surgical Journal*.

HYGIENIC EFFECTS OF SEA AND MOUNTAIN AIR.—This is the time of year when many families leave their homes in the city for the more invigorating mountain or seashore air, anxious to go where they may derive the most health-giving benefit, and still are undecided which way they will go, to the mountains or seashore. To such persons the following extract from a recent work by Dr. C. Alberto, a celebrated Italian physician, may be an aid in helping them to decide: "The marine air," says the learned doctor, "produces the same benefit as that of the mountain, but each has a different *modus efficiendi*; the former acts more forcibly and energetically on the constitution which retains some robustness and internal resources to profit by it, while the second acts more gently, with slower efficacy, being thereby more suitable to the weaker and less excitable organizations. From this important distinction, the conscientious physician, who takes the safety of his patient much to heart, ought to be able to discriminate whether the alpine or the marine atmosphere is the better suited to the case he has before him."

TO ATTAIN LONG LIFE.—He who strives after a long and pleasant term of life must seek to attain continual equanimity, and carefully to avoid everything which too violently taxes his feelings. Nothing more quickly consumes the vigor of life than the violence of the emotions of the mind. We know that anxiety and care can destroy the healthiest body; we know that fright and fear, yes, excess of joy, become deadly. They who are naturally cool and of a quiet turn of mind, upon whom nothing can make too powerful an impression, who are not wont to be excited either by great sorrow or great joy, have the best chance of living long and happy after their manner. Preserve, therefore, under all circumstances, a composure of mind which no happiness, no misfortune, can too much disturb. Love nothing too violently; hate nothing too passionately; fear nothing too strongly.—*Sanitarian*.

FOR WEAK EYES.—An exchange gives the following recipe: "Bathe the eyes in soft water that is sufficiently impregnated with spirits of camphor to be discernible to the smell—a teaspoonful of spirits of camphor to a tumbler of water. For inflamed eyes use milk and camphor, adding a little more of the camphor than above." An excellent lotion, commended by a leading Boston oculist, is a solution of ten grains of borax in the official "camphor water" (not the "tincture of camphor"). This is safe and beneficial as an application in any slight weakness or inflammation of the eyes due to exposure or weariness. In serious cases professional advice should always be taken.

SACCHARATED EXTRACTS.—C. S. Hallberg, Ph. G., in the *Chicago Pharmacist*, proposes to substitute sugar of milk as a preservative vehicle for the active principles of vegetable medicines, instead of alcohol and other substances. The advantages claimed over ordinary extracts are, that the proposed extracts do not ferment, are unchanged chemically by the contents of the stomach, are always in a convenient form, and always of uniform strength. His process is as follows: "Exhaust 16 troy ounces of a crude drug; evaporate to a solid extract; carefully desiccate and mix with sufficient sugar of milk to bring the whole when powdered to 16 troy ounces."

POTATO DISEASE AND DIPHTHERIA.—It seems now fairly established, says the *Chemical Review*, that *Botrytis infestans*, the parasite which occasions the potato disease, is the same which gives rise to diphtheria.

Annual Meeting—Safety Powder Co.

The Week.

The past week, like most of its predecessors of late, has been unmarked by local events of a noteworthy kind. The leading interests and industries of the coast are being fairly prospered, our people, in an almost entire exemption from the disease that have afflicted and the disasters that have fallen upon communities elsewhere, finding cause for special gratitude. The two great harvests, the gathering of the golden metal and the gathering of the golden grain, have gone on apace, bringing to the husbandman, and even to the gleaners in each of these broad realms of industry, ample and satisfying rewards. But while so escaping the malice agencies mentioned, we have not been spared some causes for turmoil and excitement. The political "dog days" are upon us—the partisan Sirius rises. Almost every sovereign in the land is excited, the office-seeking portion of them being wholly ravid. With three and a half parties in the field on State matters and an indefinite number of municipal tickets extant, the body politic wriggles and squirms like a basket of eels, every one seeking to get on top. All minor events are obscured by the overshadowing interest taken in public affairs, to say nothing of the still greater interest that centers in private emolument, and so patriotism prevails and all will be hurry-scurry till election is over and this scramble for official position ended.

A LETTER from Yokohama says: The Prime Minister has issued a decree that from July 1st export duties will be abolished on cotton and silk manufactures, silk and cotton mixtures, made dresses, precious stones, lacquered wares, bronze, manufactured hambo, manufactured copper, paper fans and umbrellas.]

Further About the Gold-Bearing Sulphurets.

The growing attention now being paid to the collection and treatment of the auriferous sulphurets so abundant on this coast, points clearly to a great advance of our mining interests in that direction. We made mention last week of a new method lately adopted for releasing and gathering this material from the tailings of the seam diggings that have accumulated at certain localities in El Dorado county. It appears that these sulphurets are not confined to the thin seams and ribbons of decomposed quartz that constitute this class of diggings, but that they pervade also the slates which inclose and interstratify these quartz seams, forming often the country rock on one or both sides. To such an extent have the slates at some points in the neighborhood alluded to been enriched from this source that the plan of breaking them down and crushing them after the manner of the quartz tailings has been adopted to advantage, some free gold in addition to the sulphurets being obtained by this method.

It has long been known that the slate rock which forms one of the walls of the mother lode of California is more or less auriferous for a considerable distance from the main vein. Much of this slate has in times past been broken out and crushed with profit for the free gold it contained. With the sulphurets, which abound in this rock, nothing so far as we know has ever been done. Under the impression that they were worthless or of too little value to justify any attempts being made at working them, they have probably been suffered to go to waste altogether. If, however, the sulphurets that occur in the slates of El Dorado county contain enough gold to warrant their being saved and reduced, it is fair to infer that those found in this rock elsewhere along the main gold belt will do the same. Should this turn out to be the case, then the field for practical gold mining in this State will at once be much enlarged, as this band of auriferous slate lying adjacent to the mother lode, being sometimes on one side and sometimes on the other, is very extensive. At some points in Tuolumne county it has already been worked for a breadth of 40 or 50 feet, the entire mass of slate removed having been crushed with profit. On the Harris claim, forming a section of the mother lode, and situated two miles northwest of Jamestown, an immense pit, worked as an open quarry, has been excavated in the slate, that here forms the east country. The contents of this pit were milled and yielded well, work having been discontinued only when the hole became so deep that the broken down slate could no longer be removed with a horse and cart, so little enterprise had the millmen and miners at that day.

A new mill having lately been erected on the Harris mine to take the place of the old one long since burnt down, this property is now being worked with excellent returns. Crushings since the resumption of operations have been confined to the quartz, but with these new revelations in regard to the probable value of the sulphurets in the accompanying slate belt, there is little doubt but they also will soon be attacked and that in the handling of them highly satisfactory results will be reached.

An experience not unlike this of the Harris company has been had by other parties mining elsewhere along the great quartz range that here crosses the country. In Amador county a lateral formation composed either wholly of slate or slate mixed with quartz, makes a feature of several important mines situated on the main lode between Jackson and Plymouth. In some instances this outlying material has been handled with benefit, notably so in the case of the Potosi, now known as the California mine. Besides its intrinsic value this sulphuret-bearing slate has come to be accepted as indicative of fertility in the grounds to which it forms an adjunct.

While these auriferous sulphurets are so abundant in the refuse of the quartz mills and seam diggings as well as in the rock in place, they are likely to find in the hydraulic washings of this State a very prolific source. In estimating the value of the debris or tailings that have in such quantity accumulated in certain portions of the mines, not much account has heretofore been made of the sulphurets they contain. In an elaborate report on the hydraulic tailings resting in Bear river and its tributaries, made by one of our leading mining engineers a few years since, this material was alluded to as constituting an item of no inconsiderable value. But so little was the worth of these sulphurets then appreciated that they were wholly ignored in calculating the returns likely to attend a re-handling of this debris, it being generally supposed that this engineer had attached an undue importance to these sulphurets. Recent examinations, however, show that, so far from this having been the case, their value was probably underrated on that occasion. If they carry anything like the amount of gold that recent tests indicate they will form a new and consequential factor in dealing with the problem of further utilizing these tailings, which are known to contain almost everywhere a large percentage of sulphurets. In view of their great abundance and probable value the best means and methods for concentrating and reducing these sulphurets should be at once ascertained, an end that opens a large and invit-

ing field to our own metallurgists and inventors. Both of these objects can be accomplished by the processes and appliances now in use. But these, considering the necessities likely to arise, will hardly prove adequate, being comparatively slow and costly, and therein adapted to the treatment of small quantities of rich concentrations only. There will be a call in the near future for apparatus capable of handling extensive lots of low-grade material, and the inventor who shall fully meet it will receive his reward. We are evidently on the eve of taking a step forward in the business of gold mining in California, but its success will depend in some measure upon the aid received from our skilled metallurgists and mechanical inventors; we must be able to gather these sulphurets closely and treat them with economy.

The Human Species.

In the light of modern discoveries, the problem of the origin of the human race is constantly receiving fresh accessions to the Mosaic account, notwithstanding the researches of so learned a man as Agassiz, and the delectable theories of Darwin. In order to explain the perplexities that arise from the strange anomalies that exist in the human family, Agassiz selected several centers of creation of man, giving to each of the great races a particular creative point, otherwise the Mosaic account was accepted so far as it threw any light upon the results of modern researches. Looking upon the different races as possessing nothing in common with each other, and the analogies ending with the general appearances and structure of the physical system, perhaps the theory could be maintained from a strictly material point of view. The views of Agassiz in this regard were not entirely satisfactory to him, and up to the time of his death he had not yet fully determined upon a proper solution of the problem.

It is not necessary to anathematize Darwinism, although, the descent of man from apes is revolting to all our intellectual ideas. The theory is plausible enough leaving out the immortality of the soul as maintained by equally wise philosophers, but has reference in our opinion more to the analogies existing in the animal propensities of the human race. Indeed, it is not necessary to go beyond the present time to find the intellectual faculties wholly obliterated by brutal instincts, all the more aggravated in man by as much as he is supposed to be superior to animals. There is nothing to fear from this doctrine gaining universal acceptance. It is hardly reasonable to suppose that it will become a rule of conduct in our social relations. Carried out, however, to its fullest extent, the evil consequences must be apparent to all in the total destruction of human responsibility to any superior power.

M. De Quatrefages, Professor of Anthropology in the Museum of Natural History at Paris, has lately given to the public many interesting points concerning this subject. He maintains the unity of the human species, and arrives at the conclusion that all men of whatever color belong to the same species, and that there is but one species of man. While considering some points in Darwinism—as the struggle for existence and selection—perfectly unassailable, Prof. De Quatrefages refuses to admit the descent of man from apes. The Professor does not anathematize those who maintain that man is so descended, nor does he greatly blame their boldness. For himself, however, he declares as the result of all his studies that he does not know the origin of the human species, and he believes the solution of the question is at present impossible, and will, perhaps, always be so.

As to the antiquity of the human race, he considers that discoveries warrant the conclusion that man has survived two great geological epochs, having lived during the glacial period by protecting himself with fire, and even suggests that it is possible that hereafter traces of man may yet be found further back still. He is unwilling to accept the theory of Agassiz of several centers of creation, maintaining that no facts have yet been discovered which authorize us to place the cradle of the human race elsewhere than in Asia.

He claims that the globe was peopled by migrations by land and sea, and in regard to primitive man follows the opinion of the French naturalist, M. de Salles, who attributes red hair to the earliest men. It is also argued that the ancestors of the negro were a race of a much lighter color. The Professor does not concern himself with the distinction to be established between mind and matter, and the mysterious link which unites the physical with the intellectual being, but only with the investigation of the several manifestations resulting from this connection, and with the recognition of the distinctive marks of the groups which he is studying. Avoiding this Scylla and Charybdis upon which so many philosophical theories have been and are still being wrecked, the domain of the spiritual has no place with the material, except, perhaps, as a directive power, the power of spirit over matter. In the near future, perhaps, an objective point may be reached by human investigation, which will more fully explain the relations of spirit and matter.

SALMON are very abundant in the Mokelumne river this season, and the Indians are catching large quantities on the rifles.

Our Manufacturing and Mechanical Industries.

As a glance over the physical geography of California discloses a considerable extent of arid deserts, so does an inspection of our industrial chart reveal a like expanse of barren wastes, upon which no useful pursuit has yet taken root—places where no planting has yet been done, and where it was supposed nothing would grow. At first it was generally believed that these great Saharas, lying off in the southeastern part of the State, were utterly worthless and hopelessly barren. But they are not—the soil in spots is tolerably good, the only drawback being want of water. Then, too, it is found that certain of the native products here are not without economic value. The Yucca cactus, the emblem of sterility, and about the only tree that grows on these deserts, contains a fibrous substance that makes good paper, and which is likely to be largely utilized for that purpose. And now it appears that the soil and the climate are so well adapted to the growth of the date-bearing palm that the culture of that valuable tree will soon be undertaken there. Other discoveries of like kind will probably be made; and after a while the waters of the Colorado will, perhaps, be turned on these *mauvaises terres*, so fertilizing them that we will have to eliminate them as such from the map altogether.

In like manner have our industrial wastes been invaded, and, through judicious plauting and careful culture, been much curtailed of their originally large proportions. Little by little have we encroached upon these barren and forbidding places, inducing with much care a tender plant to take root here and another there, until this manufacturing and mechanical husbandry has been placed on a firm foundation and reached respectable dimensions. To us who have been acquainted with the history of these pursuits from the first, they possess a special interest. Looking back to their small beginnings, ten, twenty, and, in some cases, as much as thirty years ago, and contemplating their struggles since, it is with satisfaction and even pride that we hail their final triumph, as evidenced in the exhibit now being made of their products at the Mechanics' fair in this city. It is within our recollection when every one of these pioneer pursuits was inaugurated on this coast. We well remember the words of good cheer and much encouragement, not un-mixed with misgivings, that were extended to them at the start.

Earliest of all was the foundry and machine business, commenced in this city just twenty-nine years ago the present month. In the Mechanics' pavilion can be seen now the first piece of iron ever cast in California. It formed part of the machinery of the steamer *McKimm*, and was made at the Union Iron Works in August, 1850, two pairs of blacksmiths' bellows having been used to raise the blast. Of such humble origin was the establishment that still bears this name outranks now all works of this kind west of the Rocky Mountains. In good time other mechanical enterprises were set on foot, all operated at first with equally imperfect appliances, and on an equally limited scale. Among the earliest articles of home manufacture were wire, cordage, soap and candles, woolen goods, earthen and wooden ware, boots and shoes, saddles and harness, paper, glass, etc.

While the most of the industries we have essayed to domesticate have turned out well, a few have proved failures; some so much so that they have been wholly abandoned, and will not be likely to undergo early resuscitation. Tea culture is not, and turpentine gathering is not. The soap plant as a fiber-yielding bulb has disappointed expectation; cotton growing languishes; the flow of our oil wells fails to keep out the Pennsylvania petroleum; and the shuttles of Lyons still keep going despite our silk growers' best efforts. Tobacco comes to us from abroad, notwithstanding the Culp method of cure and the fragrance of the Californian grown leaf. And so of many other things, which we still continue to largely import. But we have done much towards the reclamation of our economic wastes, and hope, in due time, to see their borders still further restricted. If, in the walks of high art, we are a little behind, we have still the Big Trees, the ponderous beet and the miraculous pumpkin to fall back upon. If with us the products of the pencil are not quite up to the standard of the Old World schools, our machine pictures are not to be beaten.

A LONDON dispatch states that the deposit of 750,000 francs (\$145,000) required to be made in London under the Colombian concession to the Isthmus Canal Company, before the work can be formally proceeded with, was definitely paid there on the 19th inst. to the banker appointed by the United States of Colombia to receive it.

A PROJECT is on foot in Germany for sending a large selection of German manufactured goods to South America, to be displayed in an itinerant exhibition, as a means of making the population acquainted with German manufactures and thus securing a fresh market for the same.

Antimony Deposits of Arkansas.

Recent discoveries of deposits of sulphide of antimony in southwestern Arkansas are attracting considerable attention, and the subject has seemed of sufficient importance to interest the American Institute of Mining Engineers, before which Charles E. Wait, C. E. M. E., of Rolla, Missouri, lately read an interesting paper referring to these discoveries and their magnitude. In the winter of 1874, Mr. Robert Wolf discovered a vein of ore which was unknown to him and its composition not thoroughly understood in the locality. Samples were analyzed by experts and pronounced sulphide of antimony—stibnite. Three mines have been opened since the discovery and a number of interesting minerals of the antimonial series have been found.

The three mines are situated in the northern part of Sevier county, and may be reached by the St. Louis, Iron Mountain and Southern Railway to Fulton, thence by wagon-road to Columbus, Nashville, Center Point, and to the mines. During most seasons of the year the roads are good, and the distance from Fulton to the mines is about 60 miles.

One of these mines, the "Bob Wolf," is situated about two miles west of the Cossatot river, in section 10, township 7 south, range 31 west. There is a question of doubt as to the exact time of discovery, but it seems to have been in the early part of 1874. Large pieces of the sulphide of antimony were found on the surface, which were weather-worn, but when broken showed the bright metallic luster peculiar to the freshly-fractured stibnite. Mining operations on a small scale were commenced without delay, and in a few years a hole was dug from which were taken several tons of very good ore. The ore is found in a vein nearly a foot in thickness at the surface, with strike N. 13° E., and dip approximately vertical. The veinstone accompanying the ore is quartz, stained with oxide of iron, and has received locally the name of "antimony quartz." The vein has been traced in an easterly direction for a distance of two miles, but at this point the prospect seemed to be most promising. The ore appeared in quantity, and several tons of selected ore were taken from the prospect shaft, but upon inquiry it was found that no immediate use could be made of the ore, as there were no smelting works convenient for its reduction. Such being the case they deemed it advisable to cease operations, at least until a market could be found for the mineral.

The second mine, the "Antimony Bluff," is situated in an easterly direction from the one described, and about two miles distant, on the eastern bank of the Cossatot river, on an elevated bluff in section 6, township 7, south, range 30, west. The deposit was discovered by a man named Batson, but was not given prominence until taken hold of by D. C. Ladd. It is said to be a continuation of the Wolf lode; however, there is some doubt as to the accuracy of this statement. The claim was sold to the Little Rock mining company; and in October, 1876, a shaft was commenced upon the vein, which has a strike N. 13° E., with a dip 70° N.

At the surface the vein had a thickness of several inches, but soon increased to two feet, and retained that dimension for about nine feet in depth. The rock strata through which this vein passes transversely is a very compact siliceous sandstone, while the veinstone accompanying the ore is quartz.

The ore obtained was antimony ochre—cerantite; some pieces were exceedingly pure, weighing as much as 300 pounds. The crystals in many cases have a bladed structure, resembling somewhat the sulphide, which has, in all probability, been changed to oxide. This conversion is quite evident; crystals of from four to five inches in length, and one inch in diameter, are apparently all oxide, but when fractured show a central core one-half inch in diameter of unaltered and mirror-like stibnite.

Below this depth, nine feet, the vein diminished in thickness, changed somewhat in direction, conforming more to the rock strata, and yielded ore of ochre and stibnite. At 20 feet in depth the vein was 14 inches in thickness; below this the ochre had nearly disappeared, and at 30 feet it was replaced by solid glance, the vein here having a thickness of 30 inches. At this point large masses of stibnite, fibrous in structure, were taken out, weighing from 100 to 500 pounds.

The third mine, the "Stewart Lode," is the most extensive deposit of antimony yet found in Arkansas. It is in section 4, township 7 south, range 30 west, in an easterly direction from the Antimony Bluff mine, about two miles distant, and is supposed to be a continuation of that lode. It was discovered by J. H. Anderson, in February, 1877. The surface indications in this case were quite interesting. The vein has a strike about N. 13° E., with dip nearly vertical. The ore in large pieces was exposed to view in several places within the distance of a few hundred feet. In many places in this distance the ore and quartz seemed to be a solid mass projecting above the ground.

Soon after the discovery was made mining operations were commenced. The vein was attacked on the surface for several hundred feet, and was removed to the depth of 12 feet. Some fine pieces of ore were taken from this open cut, one piece of apparently solid stibnite,

weighing 720 pounds, was shipped to Little Rock; other pieces even heavier were raised to the surface. One other piece furnished 1,250 pounds selected ore.

In order to test the character and extent of ore in this lode, several holes were dug, and in each case satisfactory results were obtained, sufficient at least to warrant a moderate expenditure in sinking a shaft. This shaft, 8 feet by 5 feet, was commenced near the eastern extremity of the cut. Some very large and pure pieces of stibnite were taken from this shaft, as well as one or two interesting minerals.

The shaft was sunk to the depth of 32 feet, and at about 18 feet two drifts were started east and west on the vein, but were continued only a few feet. Some excellent ore was taken from these drifts.

Little or no difficulty was experienced in sinking this shaft, as the formation was a black shale, easily removed with the pick, with an occasional blast.

At the bottom of this shaft the vein of quartz which carried the mineral had assumed a thickness of one foot, the ore however occupying only four inches. This mine like nearly every other mine in Arkansas has been worked only for a short season, due, in most cases to the fact that the parties interested had little or no means to invest in such precarious enterprises, at least in a new mining section with undeveloped and untried veins.

In this instance mining operations were stopped July, 1877, but previous to this time there was a general cleaning up, and the ore was selected, and placed in casks for shipment. A large amount was necessarily lost, as this separation was effected by hand. On June 20th and July 5th, 45 casks and 10 casks respective-

Fig. 1.

WEEKS' GRAPE, FRUIT

AND FLOWER PICKER. ly were gotten ready for shipment, and in all about 25 tons (2,240 pounds) were shipped to Messrs. Hallet & Co., London, for which about \$60 per ton was paid.

Grape, Fruit, and Flower Picker.

As a device now timely, we give an illustration of a fruit, grape and flower picker, which we have heard highly recommended. Its mechanism is quite fully seen by the engravings, and its use is too obvious to need comment. It is designed to save the hands from injury, which is always more or less imminent when grape-cutting by knife power is in operation. It also saves the skin from contact with the spines, with which some fruit trees are armed, and in rose gathering it disappoints the traditional thorn with which the queen of flowers is accompanied. The tool is a pair of shears arranged with an elastic holdfast that cuts the stem and holds it, so that the fruit can be deposited in the receptacle for receiving it without touching it with the hands. It is said to be so perfectly contrived that it will hold "a cherry or a bunch of grapes weighing five pounds." A point of great importance in the case of some fruits is that they may be picked and deposited in the basket without handling. Fig. 1 shows the large size picker, suitable for orchard use.

Fig. 2 shows a smaller size of the implement, which is adapted to flower picking, and which may do our lady florists good service. The pickers are known as the Weeks pickers, and are sold in this city by Dunham, Carrigan & Co., 107 Front street, S. F.

THE BRITISH CHANNEL TUNNEL.—The great tunnel under the British Channel with which it is proposed to connect England and France has not yet been fairly commenced, but the engineers have sunk a shaft near Sangatte, in order to ascertain the depth and currents of the water. When these preliminary experiments are concluded the work of making the tunnel itself will begin. The shaft now being sunk has a diameter of about nine feet, and is to go to the depth of 260 feet. Work in the shaft has been suspended for the last three months, as the water comes in so rapidly that it has been necessary to construct a machine which will extract 600 gallons per minute, or double what the machine first used could remove. The shaft has already been sunk to half the proposed depth. The walls of the shaft are being lined with small oak planks, with a backing of concrete. The earth which has been excavated is of a white, chalky nature, and very hard.

Ottoes from Citrus Fruits.

There are several subtle products derived from the fruits and flowers of the citrus family which have we believe received but little consideration in this State, but are still entitled to attention because of their place in the world's production and commerce. We refer to the ottoes derived from citrus flowers and fruits and perfumes prepared with their aid. These products are highly esteemed in other parts of the world, and supplying the demand for them returns fitting rewards to the producers. We shall therefore collect some facts about these fragrant industries and the manner of their pursuit, acknowledging our debt to foreign writers for the several statements made:

Of all scent-yielding plants none has a value at all equal to that of the orange. It is a mine of perfume in itself. The blossoms yield, according to their mode of treatment, two distinct odors, one having the true scent of the flower, the other a scent called Neroly. Orange peel, too, furnishes a delightful perfume, with which all of us are familiar; and lastly, the leaves give a scent inferior only to the true Neroly. Here then we have from one plant no fewer than four perfumes. When in full vigor each tree yields on an average 25 pounds of blossoms annually. Many plantations of orange trees at Nice are more than 100 years old. At Fontainebleau there may now be seen orange trees bearing flowers and fruit at the same time, that were planted 200 years ago. At Nice a public market exists for the sale of orange blossoms during the season when the trees are in bloom. The bitter orange flowers fetch 3d. per

Fig. 2.

AND FLOWER PICKER.

pound, those of the sweet orange 2d. At Nice the market season for such flowers generally lasts upwards of a month, and during that time there are sold from 15 to 18 tons of flowers daily! A ton of flowers will by means of distillation yield say 40 ounces of Neroly otto, worth 20 guineas; and the residuary water—orange-flower water—5 guineas. Orange-flower fat, or butter, and oil are manufactured to a large extent by the enfleurage and macerative process; it requires about eight pounds of blossoms to enflower one pound of grease, the operation being divided into about 30 repetitions of a small quantity of flowers over or in the same grease. By digesting this orange-flower grease in the proportion of six to eight pounds in one gallon of rectified alcohol, there is obtained the extract of orange flowers, a handkerchief perfume which is surpassed by no other scent; it

The 'Ecuille for Otto Making.

is exquisite in itself, and, when blended with extracts from other flowers, it composes what is termed a "bouquet."

The otto of the orange fruit is procured from the peel by what is termed the 'Ecuille process. The 'Ecuille, as shown in the engraving, is a tin-coated copper bowl, furnished with concentric rows of short spikes or teeth, and a hollow handle with a gutter from it to the edge of the bowl, through which liquid from the hollow can be poured. In order to obtain the otto, the fruit is rolled by hand over and over the spikes, thus breaking the peel in such a manner that the otto spurts out into the 'Ecuille, and finds its way into the hollow handle, which, when full, is emptied into another vessel. An inferior quality of otto is procured by rasping and slicing the peel, and then pressing out the juice; and this, and the better process just described, are those by which the fruits of all the citron-worts are divested of their scent-yielding properties, operations which are put into practice to a great extent at Messina, in Sicily.

The *Citrus bergamia*, or bergamot lemon, is a plant of great value as a scent-yielder; its per-

fume is so much in demand that its annual production in Italy has never satisfied the market. The Messina dealers and their allies carefully adulterate the true bergamot otto with lemon otto, thus spoiling an article worth from 30 to 40 shillings per pound, in order to sell it at 10 shillings. One hundred fruit will yield about three ounces of otto. The name of this variety of citron-wort is derived from the city of Bergamo, in Lombardy, from whence, so far as we can ascertain, the otto was first sold. The otto of bergamot, of the finest quality, is obtained by means of the 'Ecuille, but about four-fifths of it in the market is a distilled product, or one expressed from the rasped rind of the fruit. About 40,000 pounds of otto of bergamot are annually imported into England.

Among one of the leeward Caribbees is Montserrat, a little island on which *Citrus limetta* grows most prolifically, and in almost an indigenous manner. Under the care of Mr. Joseph Sturge the Montserrat company, of which Mr. Sturge is director, annually produces no less than 1,000 pounds of the true otto of citron, all by means of the 'Ecuille process, and it is so pure that it is worth twice its present price in the market, but the products of Sicily, which are by no means good, compete with it to its disadvantage. Mr. Sturge states that "his orange orchards consist of about 500 acres, and that each acre contains about 200 trees. It takes seven years from the seed for them to come into full bearing; they flower more or less whenever they get heavy rain, and the fruit ripens in about four months after the flowers appear." He therefore gets fruit all the year round, but the chief harvest is from September to January.

The importation of from 85,000 to 90,000 pounds of otto lemon annually into England proves that Britannia has a great liking for this scent, which is extracted by rasping the fruit and afterwards expressing the pulp so produced, of the *Citrus limonum*. The otto of lemon in the market is principally from Messina, where there are hundreds of acres of lemon groves; indeed, the extraction of the ottoes of lemon, orange and bergamot constitutes the chief industry of Sicily, particularly in the vicinity of Palermo. Here, instead of the 'Ecuille for breaking the peel, a drum spiked inside is employed, and in this 100 fruit or more are operated on at one time; no doubt, sooner or later, steam will be employed to rotate these drums, and thus we may expect the supply of these scents to be kept up equal to their demand; nevertheless, as the land of Italy is already occupied, there is ample room in European markets for similar ottoes, should they be produced in other parts of the world.

The New Patent Bill in England.

Whatever cause for complaint may exist in the United States against our Patent laws, it would seem as if English inventors considered them as near perfection. This idea crops out in the strenuous opposition to the new Patent bill in England. This bill proposes to have unpaid commissioners, an absurd and suicidal provision. Another feature of the bill is the provision to keep open the specification of a patent for the benefit of those wishing to oppose the grant of letters patent, thus keeping the invention out of the hands of poor men, who are really the only inventors, upon the theory that "necessity is the mother of invention." Wealthy men do not invent anything as a general thing, and the result would be disastrous to English industries. Besides this requirement would be a direct invitation to all interested in any certain line of manufacture to which the invention pertains, to oppose its issue by fair or foul means. Patentees are also required by the bill to work the patent within a specified time; another dab at the poor inventor. It does not seem probable that such a bill can be confirmed.

Referring to the bill in general, the *English Mechanic* says:

The inventor belongs to a class which it is becoming more and more necessary for this country to encourage, and it would be bad policy to look too closely into his profits without taking account of the benefits conferred upon the public. At present it is possible to hold a patent for 25 years, the Privy Council having power to extend the time for 14 years, but it is very rarely exercised, and an extension of any kind has to be literally fought for. It has been considered advisable to abolish this power, and to make the possible duration of all patents 21 years, depending entirely on the payment of the fees. The United States gives 17 years' protection for seven pounds, a sum which appears remarkably small when contrasted with our heavy stamp duties. It should not, however, be forgotten that we allow one patent to cover many things which in America would be made the subject of separate letters and charged accordingly; but our system needs most rectification in the scale of fees payable at the preliminary and first stage of a patent, and inventors generally would probably be satisfied with the proposed assimilation of our law to that of the United States in the matter of time if the assimilation were also extended to fees.

England is very much exercised about American mechanical progress, and will either be forced to copy after the go-ahead Yankee, or give up the commercial supremacy. The condition of the inventor in the United States is envied by foreign inventors, for the very good reason that our laws are like our inventions, appropriate.

Mineral Springs of Lake County.—No. 1.

EDITORS PRESS:—According to promise I proceed to give you and your many readers a sketch of one of the numerous medicinal springs with which Lake County abounds. In some future communications I may speak of others, but in this I shall confine myself to Anderson's, owned and conducted by the Anderson family, consisting of the venerable mother, now verging on fourscore years, her son-in-law and four daughters. The place is new, having been located only five years since by Dr. A. Anderson, of Virginia City, and the present owners. The place is as yet but partially developed, but that in the near future it will be one of the most noted and valued resorts for the afflicted, no one who will take the pains to examine can for a moment doubt. And surely, for the soul-sick, weary brain worker, or the city-imprisoned, overworked business drudge, earth holds no quieter, lovelier, or more nerve-renewing nook. There are at least 15 springs, all of different mineral and medicinal properties. The favorite drinking water of all classes is the blue sulphur spring. The water looks, smells, and tastes to me precisely as the water of the far-famed Blue Lick springs in Kentucky, and I have no doubt the medicinal properties are the same. This water, when used in conjunction with the natural steam baths, is insured by the proprietors to give relief in all cases of dropsy and kindred diseases.

Next in importance are the steam baths, prepared in nature's own laboratory. As a remedy for paralysis, sciatica, neuralgia and rheumatism, they cannot be overrated, and the inhaling of the medicated vapor must be of unknown value to lungs affected by asthma, bronchitis, or sore throat of any kind. You see there is nothing artificial about the whole thing; you just enter a hole in the mountain, and though at first the intense darkness, the heat, the villainous odors, the horrid noises, all bespeaking a nearness to Hades, anything but comfortable to the average sinner. Yet a few minutes dispels the fear, and to any in pain there comes such a relief that we forget all else. The nearly boiling stuff, I can hardly call it water, which issues from beneath this bath, is conveyed in wooden pipes to the bath-rooms of the hotel. These pipes are made by boring pitch-pine logs. The doctor found the medicinal qualities much improved by mixing with those of the pine, which are of themselves a specific in many diseases.

The white sulphur water is used in connection with the iron near by in cases of general debility and nervous prostration. The epsom salts spring is a combination of druggist's stuff, highly recommended both by the doctor and those who have used it, for dyspepsia, constipation of the bowels, liver complaints, and so on. Folks who who fancy or need them can have them for all of me. Ugh! the nauseous snuff! I am glad I am not sick, so let us trot off to the sour spring, and then go to the croquet ground and have a game. See that cabin perched on the hill yonder! That is going to be fitted up to have little surprise parties in, just near enough for the sick folks to bear the music, and too far off for them to be disturbed by the merry maker's jollity. It is pretty hard climbing to reach this same old sour spring, but no matter, we are more than repaid for our labor. Did you ever in all your experience see more truly magnificent scenery? The elevation of the mountains, the depth of the canyons, the size and variety of the trees, the multiplicity of the shrubs, bushes, ferns, vines and wild flowers. See, in one direction, Cobb mountain grandly wooded to the very top. In another direction, far above all others in height, rises Mt. St. Helena. Here the artist should come to study his art; here he would find colors the most brilliant, varied and blended in a way that even his mimic art fails to produce or copy.

A Lecture to Spring Visitors.

Can you tell me why it is that of the thousands who come to the country, and especially to the springs every year, the large majority come not to impart or gain knowledge, not to entertain or be entertained, not to rest, not to comfort or be comforted, not to set the habies free and let them have a real good time, whether that means dahlhing in the water, rolling in the dirt, clamhering over hill, dale and rock; no, no, not a bit of it. What do they come for? As far as I can see they come to do a whole year's growling, grumbling and fault-finding. The roughness of the road, the hardships of the trip, the uncouthness of the people, the heat of the weather, the abundance of the dust, but above and beyond all the horribility—I believe that expresses it, of the cooking in general, and the place they stop at in particular. Now, surely, no right thinking intelligent man or woman ever slept to dream that a country hotel was a home. Moreover, I assure these people they get the very best the country affords, and further, just because of this everlasting growl, 'tis almost impossible to get help to fix things up any better. Let us rather, as Topsy observes in "Uncle Tom's Cabin," "Think on our marcies! If they find it so hard to live a few days on the best—law blest their lot—in comparison to those whose life is spent with the worst."

These hotels are or should be a kind of school, always open where the meeting of well-bred, well-to-do, well-educated people, and an interchange of thoughts, opinions and experiences on the leading topics of the day, would give birth to enlarged ideas, higher intellectual and literary movements. Cultivate friendship; do

away with sectionalism; make us ambitious of excelling in some art, science or accomplishment, so as to enable us to take an honorable or a pleasing part in them. In this manner our time would not be wasted, and what a store of useful and pleasant memories would we not take back with us.

Lower Lake, Cal.

DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free. Address.

SEAL ENGRAVER AND DIE SINKER,

No. 439 MONTGOMERY STREET, S. F.

The best Work done on the most reasonable terms on the Coast.

To Gold Miners!

GREAT IMPROVEMENT

— IN —

Mining Apparatus.

GRATE BARS

That will Render about Double the Service of Ordinary Bars.

GROOVED RIFFLES,

A good device for taking Gold. Will also partially, if not wholly, prevent the usual loss of Quicksilver from undercurrents.

CONCENTRATOR.

An excellent device for procuring concentrations for undercurrents, Nos. 2 and 3, by

BRYAN TYSON.

For further particulars address HINCKLEY, SPIERS & HAYES, 215 Fremont street, San Francisco.

BERKELEY PROPERTY.

Residence and Business Lots

FOR SALE VERY LOW AND ON EASY TERMS

The Cheapest and most Desirable Property for Investment or for Home-estate in the State.

Lots worth \$200 sold on installments of \$5 per month. Lots worth \$300, \$10 down; installments of \$5 per month. Lots worth \$500, \$50 down; installments of \$10 per month. Lots worth \$1,000, \$100 down; installments of \$20 per mo.

Within 40 minutes of the business center of San Francisco, reached at an expense of 15 cents for single trips or \$3 for monthly tickets, being a point at which all the important railroads of the State will center, and where the University and other educational institutions of the coast are located. With fine view and delightful climate and its present rapid improvement, all combine to make this the most desirable place to locate.

Give us a call and we will give entire satisfaction, as we have property in all parts of Berkeley, and can sell cheaper than any others. Call on

S. A. PENWELL,

652 Market Street, San Francisco.

Or at residence, cor. 6th and Bristol Sts., West Berkeley.

BLANK BOOKS

MEMORANDUMS

From the celebrated J. G. Shaw Manufacturing Co. Made from the unequalled BROWN'S LEDGER PAPERS, and unsurpassed in STYLE OF BINDING.

H. S. CROCKER & CO.

W. BRUCKNER,

Mining Engineer,

Will Contract for the erection of MILLS, ROASTING FURNACES, SMELTING FURNACES, AMALGAMATING WORKS,

— ALSO —

LEACHING WORKS,

With all the Latest Improvements. Address

STATE ASSAY OFFICE,

Safe Deposit Building, Room 16, San Francisco.

Improved Grounds For Sale NEAR SAN JOSE.

The subscriber offers for sale a tract of land, 40 acres in extent, located half a mile south of the road from San Jose to Alum Rock, and four miles from San Jose—directly in the warm belt of the foothills. The grounds are pleasantly and conveniently located, and under a high state of cultivation.

Five Acres in Orchard,

—CONSISTING OF—

Orange, Lemon and Lime Trees, Nuts, FIGS, BANANAS,

Together with a great variety of other Fruits, large and small, and GRAPES. The Banana ripens readily in this locality. TWO ACRES are set off for an

ORNAMENTAL GARDEN,

Which is now filled with Shrubs, Flowers, and a fine growth of ORNAMENTAL TREES, 170 in number, now 10 years old. In connection with these grounds there is now a

Small Cottage and Farm House,

Well built and hard finished. On the higher ground there is a

FISH POND,

40 by 30 feet in extent, and 8 feet deep, well stocked with Carp and Trout. The pond is supplied with water from a never-falling spring a few feet distant, which delivers 24,000 gallons of water every 24 hours the year round. The pond is at an elevation of 20 feet above the house, and from it pipes are laid for irrigating the orchard and garden, and supplying the house.

The balance of the place is now devoted to grass and grain, but may be improved for orcharding or other cultivation if desired.

This place affords a rare opportunity for anyone desirous of securing a well-improved locality for an elegant country residence, and will be sold at a great bargain. For further information apply either at this office or of the proprietor on the premises.

C. FIELDSTED.

WASHING! WASHING!

Prices Reduced! Prices Reduced!

La Grande Laundry,

13th Street, Between Folsom and Howard.

PRINCIPAL OFFICE,

648 Market Street, S. F.

Office open from 7 A. M. to 9 P. M. Saturdays to 11 P. M. Washing called for and delivered to any part of the city free of charge.

All orders receive prompt attention. For circular and rice list apply at the Office,

648 Market St., San Francisco.

Anderson's Springs, LAKE COUNTY, CAL.

Nineteen miles from Calistoga, five miles from Middletown, and ten miles from the Great Geysers; between which and Anderson's Springs there is a good stage road.

HOT SULPHUR WATER

For Rheumatism, Paralysis, etc.; Cold Sulphur for Dyspepsia, Diseases of the Stomach and Bowels. Scenery unsurpassed. Climate mild and equable. Consumptives generally improve in health, and asthmatics are invariably relieved.

TROUT FISHING ON THE GROUNDS.

Deer Hunting in the Immediate Vicinity.

Accommodations and Cookery good. Board from \$10 to \$12 by the week.

ANDERSON & PATRIQUIN, Prop's.

CAUTION!

To Section Chimney Builders.

All chimneys on which joint bands with cement, or its equivalent, are used to make the joint smoke and fire-proof, with rods, clamps, or their substitutes, to brace the chimneys to the buildings, are INFRINGEMENTS on my patents. My patents for sectional chimneys have been sustained in every instance.

H. S. CROCKER & CO., SOLE AGENTS.

A CARD.

To Parties Interested in Mining and Milling.

Call at J. HENDY'S, N. E. corner of Mission and Fremont Streets, San Francisco, and examine COLEMAN'S PATENT SLUICE. It will save both float and flour Gold. The best system yet devised. No power required to work it. Examine it and judge for yourselves before purchasing elsewhere.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Ingersoll Rock Drills.

In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

SANDERSON BROS. & CO.'S

Best Refined Cast-Steel.

Warranted Most Superior for Drills, Hammers, Etc.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock and for sale

At No. 417 Market St., S. F., - H. D. Morris, Agent.

PATENT

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price

SETH MARSHALL, Jr., Agent,

309 California Street, San Francisco, Cal.

Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

THE ELKINS

"BOSS" GOLD AMALGAMATOR,

Is the Best, Simplest and Cheapest Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs.—heaviest piece weighs 100 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 1-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

ELKINS & LYNCH,

No. 318 Pine Street, - - SAN FRANCISCO.

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloriding Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S

Wrought-Iron Frame

FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

[CONTINUED FROM PAGE 101.]

Tybo Con, mine is looking well and yielding ore in abundance. The smelters are not in operation at present, but the mill is running steadily. It has been fully demonstrated now that the quartz ores, which were considered too light in lead to be smelted successfully, can now be milled at an excellent profit.

WINNEMUCCA DISTRICT.

OHIO LEMME.—*Silver State*, Aug. 5: The vein in the shaft of one or two claims on this ledge is from five to six ft wide and carries from two to four ft of pay ore. The other claim is being prospected by a tunnel which follows the lead. The vein in the tunnel is six ft wide and the ore streak from two to four ft wide.

ARIZONA.

TOMBSTONE.—*Citizen*, Aug. 1: The Tombstone company's mill is now running through from 15 to 20 tons of ore per day, and has already turned out over \$90,000 worth of bullion. The mill is now in good running order. While in San Francisco Superintendent White, of the Contention, completed arrangements for the erection of a mill for his company. The mill will be a 20-stamp wet crusher, with 14 pans and 7 settlers. The boiler and hoisting works for the Tough Nut will be shipped from San Francisco soon after the first of the month and put into operation without delay. The main shaft is down over 100 ft now and will soon connect with drifts from the west shaft. It will tap the vein at about 160 ft. Over 50 miners are employed on the works at present, some working eight, some nine and some ten hour shifts.

YUMA.—Reports from Silver district, near Castle Dome, are favorable. The Iron Cap mine main incline is in about 85 ft, working double shifts night and day; the quantity of ore is increasing and it looks as rich as any yet taken out, and the lowest assay yet made from this mine gave \$235, the highest, \$2,451. About 100 pounds of this metal is brought up by every shift. Men have been set at work on the Emma mine this week, and a shipment of 10 tons will soon be made. Five men are placing on the Red Cloud and have 125 sacks of selected ore.

PRESCOTT.—*Arizona*, Aug. 2: The Hidden Treasure, a mine quarter mile up the foot of the Accidental, has a shaft down 25 ft, which shows an ore vein four ft thick, that will work \$40 per ton in free gold. On the footwall is a pay streak that prospects \$200 per ton. No sulphurets have been found in the shafts, which is very fortunate.

IREMS.—*Silver Belt*, Aug. 1: An important discovery of gold and silver-bearing quartz has been made in the Santa Catarina mountain by S. D. Ramsdell. An assay gave \$75 gold and \$73 in silver. The ledge is reported as averaging 100 ft wide.

GLOBE DISTRICT.—Richmond Basin mines are steadily improving, and it is now evident that the rich ores are inexhaustible. The Mack Morris is the center claim as it is also the "Bonanza" of the district. Independent of the main ledge, three others exist on this claim running nearly parallel with, though dipping toward it, carrying the same character of ore as the main ledge, thus showing they all come from the same source. The first-class ore worked from this mine gave an average of \$3,000 per ton, while smaller lots of picked ore have run as high as 6,200 ounces. This mine is rendered remarkable from the fact that the ore is uniformly rich and extensive from end to end of the claim and from top to bottom of every shaft, the number being six in all. Ore is now being extracted from the new shaft of the west end of the main ledge, thus giving \$12,000 to the ton. To the south of this mine is situated the Silver Nugget running almost at right angle to it, the north end commencing at the south side line of the Mack Morris, consequently all veins of the Nugget pass through the side ground of and terminate in the Mack Morris lode. The Silver Nugget has gained a wide reputation as a silver producer, having had large quantities of ore worked that gave from \$3,000 to \$20,000 per ton.

YAVAPAI.—*Arizona Miner*, Aug. 1: We were shown to-day specimens of ore from the Golden Chariot and Harriburg mines, which are nearly one-half gold. These mines are situated on Groom's creek, about six miles from Prescott.

COLORADO.

NEEDLE MOUNTAIN.—*San Juan Prospector*, Aug. 2: The Corsair lode, owned by Chicago parties, is a promising mine, and shows very rich streaks of mineral. Assays of 250 ounces to the ton in silver have been obtained from this lead. The Occidental lode, another of the properties of the Chicago company, has given a mill run of 96 ounces.

MINERAL CITY.—Kurlig & Nelson have just completed their contract of sinking a 25-ft shaft on the Devenport and have commenced work on the Wicker, an extension of the Boston, owned by F. J. Pratt & Co. W. Boot & Co. have several claims on their mines, viz: The Thunderbolt, British Queen and Pride of the West. In the Great American, an extension of the Eighth Wonder, some very nice carbonate ore is being taken out, while farther on, on the same vein, W. McWay, of Cherokee, Iowa, is engaged in working the Graham lode, taking out pay ore. The Palmetto, located about one-half mile from the Eighth Wonder, is being worked with a large force of men and the ore, which is very high grade, is being shipped to the Los Mills at Capitol City. Burro trains pass here daily, loaded with ore from Tabor's mines. A cabin has been built on the Big Giant and new contracts let to Pat McEnany. The present developments are a 50-ft shaft and 114-ft tunnel. Some beautiful gray copper was taken out last week which assayed 271 ounces to the ton.

VERMILION COUNTY.—*Prospector*, Aug. 2: On Wednesday last a Mr. Marietta who has been digging a hole in the Carbonate district north of the Baltic lode, and not far from the Rambler, struck a very good body of ore at the depth of 52 ft, which showed up by actual mill run 27 ounces of silver per ton. On the Iron Mountain a three-ft vein of mineral was uncovered yesterday that looks very rich. From the Silver King a mill run of 570 pounds of vein water was secured, giving 44 ounces of silver per ton. A mill run from the Last Effort, 600 ft east of the Rambler, at a depth of 52 ft, shows 27 ounces. The Quaker City, northwest of the King of the Valley, is showing up very beautiful at 25 feet. An assay has been obtained showing 40 ounces to the ton. The ore is in abundance. The Tontine, seven miles east of the city, is showing up splendidly, and bids fair to become an extremely rich paying mine. The dump now can be sold, though the shaft is but 10 ft, at a very handsome sum per ton. The Cora Lillie, an extension of the Bull-Domingo claim, belonging to the Marsden Bros., is being sunk, parties having commenced sinking the shaft this week. The shaft is now down 20 ft. The same body of ore as that found in the Domingos-Bull mine will undoubtedly be reached within 10 or 15 ft. The Bull mine is being worked actively and huge piles of rich ore are being taken out.

IDAHO.

YANKEE FORK.—*World*, Aug. 1: The first shipment of ore this season was sent out on 158 mules a few days ago. There were 25 tons of it, worth \$300 per ton. E. M. Wilson lately returned from the Saw-Tooth range, bringing ore that assays \$1,000 per ton.

MONTANA.

BEAR DISTRICT.—*New Northwest*, Aug. 7: The country around Bearfoot has been known for some time to have good quartz. In First Chance and other gulches a large number of leads have been located and developments made shows that the quartz-gold-bearing exists in large quantities. Of late there has been considerable excitement over a reported discovery in Washoe gulch, at the head of Bear and north of First Chance gulches.

IREMS.—*Miner*, Aug. 5: The shaft sunk on the Stevens, 200 ft east of the main shaft, has reached the depth of 35 ft. It shows a well-defined lode, six ft wide, and similar in all respects to the portion cut by the main shaft. A calcining furnace, rolls, Blake crusher, etc., of the O. & M. smelter are at work preparing the first lot of ore for the reverberatory, which will probably start up in about

ten days, perhaps less. Glendale letter of the 20th ult. says: The large furnace is running and has turned out since the fire eight car loads, which average 400 ounces of silver per ton, equal to 4,000 ounces per car load, since 10 tons makes a car load. There is now on hand 150 tons of copper matte ready to be crushed. In the Twin Stevens' lode opened with a 40-ft shaft to water level, and 50 ft to the east from bottom of shaft. The level shows a 16-inch vein of high grade smelting ore, of which a small lot has already been delivered at the works of the C. & M. S. Co. Salton Cameron, of the Cable district, has lately ordered from the East a five-stamp mill to be put upon a mineral deposit of singular character lately struck a few miles below Cable. Instead of a vein or lode as in the ordinary type of the Montana mineral-bearing rock, the new discovery appears to be of a widely different formation, consisting of a limestone country rock, through which pockets of rich ore are dispersed so thickly as almost to touch one another. The territory embracing this formation is about 400 yards square. Very shallow prospecting shafts brought to light so large an amount of very high grade ore that Mr. Cameron, an experienced miner of very cool judgment, considered himself abundantly justified in ordering a mill at once, without waiting to explore to greater depth. Appearances indicate a most valuable discovery in this new departure in Montana ore deposits.

New Curiosities at the Smithsonian Institution.

A number of interesting specimens have, according to the *Washington Republican*, been recently added to the ethnological division of the Smithsonian Institution, among the most important of which are the following: A carved figure of a man's head, made from iron pyrites. It was found in southwestern Mexico, and is supposed to have been an amulet, belonging to a great cazique, during the reign of the Aztecs. The work is highly polished, and presents a beautiful green and gold appearance. The eyes, nose and teeth are brought out in bold relief, the former being composed of opals, which gleam like sparks of fire. The features are of the most pronounced Aztec type. In a large cave, about two miles from Silver City, Col., there were found some specimens of ancient remains, which are supposed to have been made by the Pueblo people. They consist of arrows, which still have remnants of their sinew shaftings, rain gods, and fetiches in carved and painted wood, tripartite, and bundles of straw bows and arrows. All these articles are in a remarkable state of preservation, and it is thought that the cave in which they were found was formerly used as a burial place. The entire collection was presented to the Smithsonian, and will be placed on exhibition in a few days. Probably the most important relic that has been added to the museum in a long time is an obsidian vase, made from itztle, or volcanic glass. The workmanship on the vase is perfect, not a flaw having been discovered in the work. It represents a monkey in a sitting posture, with his head bent slightly forward. In the back and shoulders are apertures in which articles for ornament were placed. The carving is exquisite, and shows what perfect lapidaries the semi-civilized people who made it were, as the material of which it is composed is considered the hardest to work in, owing to its brittleness. This relic was also found in the Aztec country of southwestern Mexico.

On the first floor, in the main hall, stands another curiosity which deserves particular attention. It is a large case, nine feet by four and one-half wide, containing numerous species of snakes, all of which are alive. Through the top, which is covered with glass, the movements of the reptiles can be plainly seen. The cage is filled with stumps of trees, grasses, ferns and sand, and an artificial lake keeps the ground continually moist. There the reptiles have full sway, and although somewhat repulsive, their cage is always surrounded with curiosity lovers. Some of the varieties are: Coachwhips, indigo or gophers, chicken, black and garter snakes. A king snake is also among the collection, and has to be carefully watched, as he is fond of hugging his companions, and very frequently kills them, after which they make a meal for his highness. This snake is the mortal foe of the rattlesnake, who always comes out second-best in their fights.

The work on the annex to the Smithsonian, in which are to be stored the Centennial exhibits and contributions from foreign governments to the United States, progresses rapidly, a large force of workmen being employed. The brick work on the lower story is nearly completed, and the beams for the floors will be placed in position during this week. Nearly two and a quarter acres will be covered by the new building, and when completed it will be a great ornament. A visit to the Smithsonian will well repay all lovers of interesting and curious relics.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Alexander, Aug. 8th, \$8,119.37; Martin White, Aug. 6th, \$4,975.72; Belle Isle, Aug. 11th, \$20,000; Independence, Aug. 11th, \$4,000; Ophir, Aug. 6th, \$58,763.89; Sierra Nevada, Aug. 8th, \$45,347.76; Northern Belle, Aug. 6th, \$3,955.29; California, Aug. 7th, \$74,164.69; Florida Hill, Aug. 7th, \$3,455.52; Hillside, Aug. 10th, \$4,500; Northern Belle, Aug. 9th, \$5,419.34; Con. Virginia, Aug. 11th, \$40,630.70; Martin White, Aug. 10th, \$6,280.35; Hillside, Aug. 13th, \$4,500.

PATENTS AND INVENTIONS.**List of U. S. Patents Issued to Pacific Coast Inventors.**

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

FOR THE WEEK ENDING AUGUST 5TH, 1879.

218,211—SAFETY ATTACHMENT FOR CHAINS—R. Y. Anderson, Santa Clara, Cal.
218,164—CATARRH APPARATUS—Geo. W. Corey, Cheyenne, Wyoming Ter.
218,173—HARROW—S. Harris, S. F.
8,830—CARPET SEWING MACHINE—J. Hesse, S. F., (re-issue).
218,127—GRUBBING MACHINE—S. G. McCann, Corvallis, Ogn.
218,231—POTATO CUTTER AND DROPPER—T. Labrec, Castroville, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

PIPE JOINT.—J. P. Culver, San Francisco, and T. H. Walsh, New York City, dated July 29th, 1879. This invention relates to improvements in the construction of asphaltum and cement pipes, and it consists in forming the ends so that a cold-lead-calked joint may be made without breaking the pipes. In the construction of this class of pipes the ends of each section are enclosed by an iron band which protects them when being handled. An iron sleeve, somewhat larger than the iron bands, is supported around a mandrel of the size of the exterior of the pipes. This space between the sleeve and the mandrel is then filled with molten lead, or other soft packing metal, and when cool the sleeve, with its lining of soft metal, is removed from the mandrel. When pipes are to be laid, one end of each section is slipped into this sleeve and the soft-metal packing is then calked so as to make a tight joint.

SAFETY ATTACHMENTS FOR CHAINS.—Richard Y. Anderson, Santa Clara, Cal., dated Aug. 5th, 1879. The object of the inventor is to produce a safety attachment for chains, intended more particularly to make connections between chain or cable and mining huckets or cars, but it may serve for other purposes. The invention consists in forming the shank of the hook of considerable length, and placing the hole through which the chain crank passes near the outer end of the shank, so that the hook will at all times swing transversely to the chain on which it hangs, thus reducing the liability of disengagement of the hook. A sliding plate is placed upon the link above the hook, which prevents the passage of more than one link through the eye of the hook. This device has been used at the "Little Pittsburg mine," in Colorado, and several other places, and gives general satisfaction.

ELEVATOR.—E. D. Haven, Portland, Ogn., dated July 29th, 1879. This invention relates to certain improvements in that class of elevators which are employed in stores and buildings; and it consists in the combination of an outer and an inner frame or cage, the inner one resting upon springs within the outer one. Each of these frames or cages has an independent set of safety catches, which are operated successively if the rope breaks or the elevator descends too suddenly. In addition to these, a supplemental device is provided which may be controlled by the operator or passenger.

POTATO CUTTER AND DROPPER.—Thomas Labrec, Castroville, Cal., dated August 5th, 1879. This device relates to an improvement in potato cutters and droppers; and consists in providing a case or box which may be mounted on the beams of a gang or sulky plow, the box carrying a cutting knife, which is operated by a lever moved by cams on the wheels, so that the potato is cut into two pieces, and one piece dropped at a time into the furrow behind the first plow so as to be covered up by the second one.

HARROW.—Silas Harris, No. 7 Liberty St., San Francisco, patent dated August 5th, 1879. This invention consists in making the bars holding the teeth of what is known as "channel-iron," and providing a peculiarly made spring clamp between the flanges of the iron, which holds the teeth firmly in place. Wheels are provided, which are attached to the teeth at the corners so that the harrow may be moved to or from the field, when they may be removed and placed upon the upper end of the teeth in an adverse position.

ROAD locomotives are said to be coming generally into use in France; lately a 12-ton locomotive (portable engine) was harnessed to a piece of artillery weighing 43 tons, which it brought from Vincennes to the point d'Austerlitz. This same engine is meant to carry to the plateau at Châtillon armor-plated towers, in sections weighing 30 tons each.

News in Brief.

THE Kuldja question has been settled. The Zulu king has not offered to surrender. GERMANY intends to adopt silver as money. TENNESSEE has voted to repudiate her debts. YELLOW FEVER has slaughtered 11 Americans at Hayti.

ANOTHER Montreal bank hurst, the Villis Marie. \$700,000 gone. A NEW town named Beulah is to be laid out at the Mineral King mines.

FRANCE, Italy, Spain and Portugal show an immense deficit in silk crops.

A NEW race of men has been discovered in the northeastern part of Siberia.

A BANKERS' CONVENTION is being held at Saratoga, to discuss taxation of banks.

DR. CHARLES BEARDSLEY has been appointed fourth auditor of the treasury.

THE river Mersey has overflowed, and caused much damage to crops in Lancashire.

GAMBETTA's fate cost \$30,000. One more victory for freedom and increased taxation.

J. BOLIER, who grossly assaulted a child 11 years of age at Fort Fairfield, Me., was lynched.

THE 14th Mechanics' fair, now in progress in San Francisco, is said to surpass all former exhibitions.

THE drouth is such in Shreveport that many citizens are compelled to buy water for drinking purposes.

REV. DR. LAWRENCE McMAHON was consecrated Bishop of Hartford diocese yesterday in St. Joseph's Cathedral.

IT is stated that V. L. Gibson, late cashier of the Citizens' National Bank, Detroit, is short \$20,000 in his accounts.

THE Indianapolis tile works were destroyed by fire Saturday night. Loss, from \$30,000 to \$40,000; insurance, \$30,000.

A NEW trial, in the suit of Whalen against General Sheridan, for damages during the war, has been denied the plaintiff.

THE hilliard pool championship match, between Knight and Morris, at New York, was won by the latter—21 games to 19.

THREE THOUSAND miners of Silverdale, North Staffordshire, have struck against an increase of hours and a reduction of 10% in wages.

LARGE amounts of United States funded bonds are being freely taken up in London on American account, and shipped to New York.

TRADE in California wines is increasing in New York; fully 1,000,000 gallons of wine, and 100,000 gallons of brandy have been shipped so far this year.

A CALL has been issued for a Prohibition State Convention at Altoona, Pennsylvania, September 9th. It is expected a State ticket will be nominated and an address issued.

THE warm weather has considerably improved harvest prospects in France. French producers are frightened at the decline in prices of French wheat, caused by heavy imports from America.

SAFETY PASHA has promised the Greek Minister that the Porte will appoint commissioners to negotiate relative to the boundary, although it would prefer to have the matter settled by the mediation of the Great Powers.

MAMMOTH CITY, Mono county, is between 10,000 and 11,000 feet above the sea level. Though within the regions of perpetual snow, the winters are spent comfortably, and last winter's work was hardly suspended for a day.

THE Virginia Enterprise says: A chicken has been hatched on the Divide with two heads and three eyes. One eye is located between the two heads, and the other eyes are placed on the outside of the heads. [This is the Cyclops.]

IT is said that the San Diego Indians will celebrate the feast of San Luis Rey at Pala on the 27th inst. The celebration is expected to be a grand affair. A great many whites will be present. Bull fights will be among the chief attractions.

THE Rumpu disaffection in India is spreading. The insurgents are badly armed, but conduct a guerilla warfare. Operations against them will not be successful until after the rainy season is over, when troops can follow the insurgents into their fastnesses.

SOME Italian gardeners near Stockton lately poisoned a number of melons for the benefit of the parties who were in the habit of foraging on them nights. Some of these melons got into the hands of innocent parties, and two children have been poisoned in consequence.

THE Los Angeles Commercial says: Gold continues to be found in the northwestern part of the county, where the first gold ever known in California was discovered and sent to Philadelphia by the late Don Ahel Stearns. A nugget of the value of \$400 was discovered Thursday, by a Spaniard, about seven miles from Newhall.

INDIUM.—Indium is apparently the most valuable of known metals, as the following comparisons of value will show. For instance, one pound of indium equals in value 8½ pounds of gold; 2½ of platinum; 135 of silver; 1,018 of nickel; 1,654 of mercury; 6,617 of antimony; 7,780 of tin; 10,180 of copper; 17,650 of zinc; 24,070 of lead, and 132,354 pounds of iron.

THE government of Guadalupe, West Indies, offer a prize of 100,000 francs to the successful inventor of a new method of manufacturing sugar, by means of which more than 14% of sugar can be obtained from the cane. It is distinctly stated that the improvements are not to apply to present machinery, but to an improved method of manufacture.

Mining District at Sullivan, Maine.

In a paper upon the above subject, read by C. W. Kempton, mining engineer, of West Sullivan, Maine, before the American Institute of Mining Engineers, it appears that the above district has been in process of development for the past ten months.

The district is in southeastern Maine, and extends from the town of Franklin, through Ifanecock, Sullivan and Gouldsborough, from northwest to southeast, about 16 miles. Sullivan is situated at the head of Frenchman's bay, 10 miles from Bar Harbor, Mount Desert, 12 miles from Ellsworth, and 37 miles from Bangor.

The staple production is granite, and first impression would declare that no other kind of rock existed there, but closer examination reveals more slate than granite, and that the mineral veins of the district are found along or near their line of contact. The slates of the region are quartzitic, of unknown age, undoubtedly very ancient, and referred to the later Laurantian—the limbo to which most of the doubtful New England rocks are assigned. Through these have been thrust the immense mass of granite and its allied rocks, from which action has proceeded the formation of the principal mineral deposits.

The first discovery of silver ores here was made by Mr. A. A. Messer, in May, 1877. They were discovered below high-water mark, on the shore of the bay, at the site now occupied by the shaft of the Sullivan mine. The vein, when found, showed about 10 inches of quartz, carrying pyrites, galena, and traces of brittle silver (stephanite).

A coffer dam was built and shaft commenced. The first native silver threads were found about 10 feet down. The vein was uncovered in several other places, also below high-water mark, proving that the showing at the shaft location was the poorest yet found. Seventy-five feet from the shaft, southeasterly, the quartz is four feet wide at three feet below the beach, and the lowest assay known from this is over \$200 per ton in silver. The ore is principally stephanite.

Proceeding with the shaft, at about 30 feet depth, the vein, composed of quartz, with more or less slate highly impregnated with sulphides, was found to be four feet wide. At this time the shaft is 100 feet deep. Drifts have been run 62 feet southeast from the 75 level, and 30 feet northwest from the 55 level. About 600 tons of ore are on the surface ready for concentration. The ore is essentially silver, sulphides and native, in quartz and silty gangues, with slight amounts of iron, zinc, etc., as sulphides, and also galena.

Of the silver minerals, stromeyerite is most plentiful, stephanite next, argentite (silver glance), common, native silver in flakes very plenty, threads frequent, lumps occasional.

Ruby silver is exceedingly rare; antimonial silver has been found. The occasional yellow copper sulphide met with has a peculiar luster and runs very rich in silver.

Arsenical iron abunds, showing gold, and giving, in some cases, an assay for silver.

Less than a year has sufficed to demonstrate the existence of strong fissure veins in this district, carrying high-grade ores, and to give every assurance of their permanency and value. The level surface of the country, covered with drift gravel, makes prospecting a slow matter.

A Library for Inventors.

We have at our patent offices, No. 202 Sansome street corner Pine, a complete set of Patent Office reports, containing engravings and claims of EVERY PATENT ever issued in the United States.

We have also a complete set of the MONTHLY VOLUMES issued by the Department, with full detailed description and large drawings of all the patents issued since the time when these volumes were first published.

A set of all the LAW BOOKS ON PATENTS is also on our shelves ready for reference. We have also the British Commissioners' reports, Canadian Patent Office reports for all British North America, full files of MINING AND SCIENTIFIC PRESS, PACIFIC RURAL PRESS, Scientific American, Scientific American supplement, American Artisan and other American and foreign scientific and mechanical journals, as well as mechanical dictionaries, chemistries, encyclopedias, and other works of reference.

Inventors and patentees are WELCOME TO EXAMINE at their leisure any of the books in the above sets, and we shall be glad to give them any assistance in hunting up what they want.

Our library is the most complete of its kind on the Pacific Coast in every respect, and we are continually adding to it as occasion demands. DEWEY & CO.,

Patent Agents and Publishers,
No. 202 Sansome street, corner Pine, San Francisco

Acknowledgement and Thanks.

LAKEPORT, Lake Co., Cal., Nov. 2d, 1878.

Messrs. DEWEY & CO.—Gentlemen:—I hereby acknowledge receipt of patent, for which please accept my sincere thanks. When I have any further business in this line I shall certainly employ you. With kind regards, I am, Yours very truly, CHAS. SLATTERBECK.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Friebe, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	2 Complete volumes, 1st half (of year).
1870	20	2 Copies of No. 2, Jan. 1st.
1870	20	1 Copy each of No. 1, Jan. 1st, 3 of Jan. 14th, 7 of Feb. 11th, 6 of Feb. 18th.
1871	21	5 Copies of No. 1, Jan. 7th.
1871	22	3 Copies of No. 5, Feb. 4th.
1871	22	1 Copy of No. 3, Jan. 21st, 6 of Feb. 21, and 1 of May 1st.
1871	23	1 Copy of No. 2, July 15th, and 6 Sept. 2d.
1872	24	2 Copies of No. 4, Jan. 27th.
1872	24	3 Copies of No. 7, Feb. 17th.
1872	24	2 Copies of No. 17, April 27th.
1872	25	1 Copy of No. 10.
1872	25	1 Complete volume, 1st half (of year).
1873	26	3 Copies of No. 8, Feb. 22d.
1873	26	3 Copies of No. 9, March 1st.
1873	26	2 Copies of No. 10, March 8th.
1873	26	1 Copy of No. 7, Feb. 15th.
1873	27	3 Copies of No. 20, Nov. 15th.
1873	27	4 Copies of No. 21, Nov. 22d.
1873	27	3 Copies of No. 24, Dec. 13th.
1875	30	1 Copy of No. 4, Jan. 23d.
1875	30	1 Copy of No. 5, Jan. 30th.
1875	30	1 Copy of No. 8, Feb. 20th.

EVERY new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

Quicksilver Mining Publication.

Memoir on the Mines and Works of Almaden, by M. H. Kuss, M. E. Translated from the "Anales de las Minas" for the MINING AND SCIENTIFIC PRESS by H. CHERRY. CONTENTS.—PART I. Geological Description of the Deposits at Almaden: 1. Introduction; 2. Geological Situation and Constitution; 3. Strata; 4. Devonian System; 5. Eruptive Rocks; 6. Deposits of Mercury; 7. Description of the Mine; 8. Mineralogical Constitution of the Vein Matter; 9. Age of the Veins; 10. Abandoned Mines. PART II.—Exploitation of the Mines of Almaden: 1. Method of Exploitation; 2. Organization of Labor; 3. Mechanical Preparation. PART III.—Metallurgy of Mercury at Almaden: 1. Description of the Works; 2. Treatment of the Ore; 3. Losses of Treatment. PART IV.—Administration and History: 2. History; 48 large pamphlet pages, post-paid, 50 cents. DEWEY & CO., Publishers, S. F., 1879.

SOUTH PACIFIC COAST RAILROAD.—This popular line has made a reduction in rates between San Francisco and San Jose and Santa Clara, to take effect April 1st, 1879, viz: Regular local tickets between San Francisco and San Jose, \$1.75; Santa Clara, \$1.65. Round trip tickets (good until used) between San Francisco and San Jose, \$3.25; Santa Clara, \$3.05. Excursion tickets sold Saturday afternoons and Sunday mornings from San Francisco and Park street, Alameda, to Santa Clara or San Jose, and return, \$2.50; good only until Monday evening following date of purchase. Commutation tickets good for one round trip daily during calendar month, between San Francisco and San Jose, \$20; Santa Clara, \$10. Family tickets for 10 rides and 30 rides, also six months and yearly commutation tickets on sale at corresponding reduction in rates. GEO. H. WAGGONER, Gen'l Pass. Agent.

THOS. CARTER, Superintendent.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicum. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

How to STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

PRINTER'S PROOF PRESS, complete and in good working order, for sale at this office, at the low price of \$30. Call and see it.

EXPERIMENTAL MACHINERY, drawings, patterns, models, all kinds of electrical and telegraphic apparatus to order. See ad. F. W. FULLER, 415 Market St., second floor, S. F.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts

Mining Machinery Depot,

PARKE & LACY,

No. 417 Market Street, San Francisco.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

FRASER & CHALMERS
 STEAM ENGINES, BOILERS, STAMP MILLS, FRUEVANNERS
 (and Machinery) for Systematic Mining, Milling, Smelting and Concentration of Ores.
 No. 145 Fulton St., CHICAGO, ILL.

Patented June 25th, 1878.

RUSSELL'S AMALGAMATOR.

SAVE YOUR GOLD And Also SAVE YOUR QUICKSILVER.

The above Washer and Amalgamator with new patent Wire Bridge Quicksilver Boxes attached, can be worked wet or dry, either by hand, steam, horse or water power, and is easily taken apart and packed. For washing Pulp, Earth, Gravel, Mill Tailings or Black Sand, it is without a rival.

Has been Thoroughly Tested and given Complete Satisfaction.

The entire Lining, Hanging Plates, Riffles and Boxes Amalgamated

IS GUARANTEED TO SAVE THE FINEST OR FLOAT GOLD.

Capacity, 30 to 60 tons per day, according to size. For further particulars apply to

J. MORIZIO, Gen'l Agt.,

Room 24, Safe Deposit Building, Corner Montgomery and California Streets, SAN FRANCISCO.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated. With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, PROPRIETOR.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

The New Era in California Gold Mining.

In contemplating the subject of gold mining in California, the impression largely prevails that the business has now seen its most remunerative and prosperous days. Remembering or hearing tell of the times when men gathered the precious metal by the ounce, and even this pound, daily, with only the pan or rocker, most people are apt to conclude that this was the true Golden Age of California; and, that having passed away, nothing like it will ever be experienced here again. And so, hemoaning the flush days of the Argonauts, the present generation relax their efforts and suffer their opportunities to pass by unimproved. Because they cannot go out and with these simple implements make the big wages of pioneer times, they feel disinclined to put forth a vigorous effort and turn to the best account the chances that still remain. Let, however, these worshipers of the past remember that this is a world of compensations, and that while the advance gold-digger was able with only these simple aids to realize very liberal pay with very little labor, he had to prosecute his calling subject to many disadvantages and drawbacks; so many, in fact, that his life may be said to have almost reached a maximum of discomfort while his revenue was often reduced to a minimum of net earnings. If his income was large, his outgo was in proportion, rendering the margin for clear gain hardly larger than at present. The average miner of that period was an itinerant sort of person, homeless, reckless, addicted to many reprehensible habits and much subject to disease, as witness the tenantry of the primitive graveyards.

It is true, men cannot now go into the mines and find paying claims as readily as aforesaid; nor, when found, can they without some capital open and work them to advantage. More money and time are required now to make a start in the business than were necessary in former times. But then, the business once started, pays at present with more certainty and quite as largely as ever before. To the patient operator, having some means, the chances for making money at gold mining in this State are better now than they were a quarter of a century ago. Skill and capital have in large measure taken the place of sheer strength and muscles, and, having now the benefit of long experience, are bound to reach results that will make former returns look poor and small. But while science and money are going to so advance production, the bar-handed miner is not going to be retired from the field. A better day is coming for him as well as for the employer of large means and educated methods. In the simplified processes and cheapened machinery, coupled with the great abundance of pay material likely to present itself in the shape of auriferous sulphurets and quartz, hydraulic tailings, beach sands, etc., the poor man's opportunities are coming back to him, even here in California. It is possible today to place a quartz mill of 10-ton capacity on a mine in almost any part of the State, at an expense of hardly more than a thousand dollars, while apparatus for reducing ordinary gold-bearing sulphurets or rewashing the hydraulic tailings can be supplied and set up for even a smaller sum.

Let those who are sceptical on this point go to the Mechanics' fair, now open, in San Francisco, and see what has been accomplished in this line of improvement, and they will no longer doubt the truth of this statement. It might be wise for those especially interested in this subject to supplement such visit by an inspection of the various foundries and machine shops in the city, where also much can be seen illustrative of the progress lately made in this department of invention. Surveying the whole field, and considering the sum total of the gains here adverted to, we really believe they denote such an advance in the business as may be justly termed a new era in California gold mining.

The United States produces annually 200,000,000 pounds of wool, and imports for manufacturing purposes about 50,000,000 pounds. We manufacture four-fifths of all goods made of wool which enter into the world's consumption, and use our own wool for four-fifths of that manufacture.

An Improved Pipe Threader and Cutter.

We illustrate herewith the latest improved Saunders' pipe cutting and threading machine, imported by Dunham, Carrigan & Co. This is a very ingeniously contrived, substantial and thoroughly fitted machine, very well adapted for general use. When a job of any magnitude is to be done, a large saving of labor is effected by it. It will be found that it is easier on both dies and pipe, and also on workmen, than the ordinary way of cutting and threading; three times the amount of work can be done on large sizes than by hand in the same time.

The machine is portable, weighing about 400 lbs. The arrangement of the gearing permits of the machine being adjusted to the work to be done, enabling one man to screw two-inch pipes with ease. There are three changes of speed. The fast speed cuts $\frac{1}{4}$, $\frac{3}{8}$ and $\frac{1}{2}$; the next, $\frac{5}{8}$, 1 and 1 $\frac{1}{2}$ inches; and the slowest, 1 $\frac{1}{2}$ and 2 inches. The changes are made by the movement of the lever in front of the machine. The patent concentric gripping chuck is of substantial construction, having three jaws moved to the center by one screw—centering the pipe true. The machine is provided with a novel chuck on the back end of the spindle, for centering the pipe, doing away with guides. The die head is arranged with cutting off tool slide, and self-centering jaws, for steadying pipe while being cut off. The die starter is the long lever-working pinion in the rack at the bottom of the die head. Crooked threads can not be cut, as the pipe revolves, and the die stands still. There are no loose guides to be changed or lost. The machine can be easily arranged to operate by belt power when desirable.

SAUNDERS' IMPROVED PIPE THREADING MACHINE.

The system adopted in the manufacture of these machines enables the agents to readily duplicate parts requiring renewal, and to fit them up in a superior manner. It also permits them to offer them at a price not very much in excess of the cost of a set of stocks and dies cutting the same range of sizes, with the necessary cutting-off tools and pipe vise, all of which it will to a great extent supersede; especially in a shop of some size. The device is also an excellent one for machine and jobbing shops for cutting off round iron or steel, and with the bolt-threading and nut-tapping attachment it makes a very good bolt-threader and nut-tapper. The machines are made for hand or power, or for both.

Petroleum as Fuel.

From all accounts it would seem that the use of petroleum as a fuel for steam boilers seems to be a success. The result of experiments that have been made are highly favorable. There does not seem to be anything particularly new in this manner of using it, the use itself being the novelty.

A spray of petroleum and a blast of air, both projected by steam into the furnace, produces a roaring flame, and when once started, keeps the fire going; but some minor improvements, intending to keep the quantities of the three substances named in proper proportion, so as to produce the maximum heat, appear to be the peculiar improvements which made this long-sought process successful.

A small steamer at Pittsburg, Pennsylvania, was recently selected for the test. The small quantity of steam necessary to start the burner in operation was raised by a small wood fire. The oil valve was opened a trifle, as was also the steam valve. The petroleum trickled into

A New Ore Crusher.

The Huntington Ore Crusher is a new invention, just being introduced, and has attracted great attention from milling experts by its rapid and efficient work. Inside the cylinder, or, in case, is a grooved die, completely encircling the case. To the center horizontal shaft are secured transverse bars, which have swinging arms pivoted to them. These swinging arms are furnished with crushing balls or rollers, which are caused to impinge on the grooved die by centrifugal action, caused by rapid rotation of the shaft.

Scrapers are attached to the bars carrying the swinging arms, and serve to keep the ore from packing and to stir and throw it up against the dies. The hopper has double openings, so that the ore is fed to the rollers and dies from both sides at once. The bearings of the rollers are constructed in a peculiar manner where they are connected with the swinging arms, so that dust or grit is prevented from entering the journals. Where the driving shaft passes through the sides of the cylinder, the construction is such as to prevent any wear or cutting from grit.

The ore fed in through the double hopper falls on to the beveled edge of the case, and is directed from both sides under the shoes into the groove of the die. The rollers, by the rotation of the shaft, fly out against the grooved dies, and pulverize any material which is in the cylinder. The scrapers do not admit any accumulation of ore at the bottom of the die, but keep it distributed and stir it up so that the rollers are not crowded. The rapid rotation of the rollers and the action of the die distribute the ore in every direction, which, when crushed sufficiently fine, is discharged through screens from both sides.

The centrifugal motion imparted to the crushing balls is such as to keep them in contact with the grooved die for the entire circle, and the flying particles of ore are therefore crushed over and over again, until fine enough to pass the screens. The circle of dies may be removed at any time when necessary. The machine is adapted for either wet or dry crushing, a feature which is novel in this class of machines. The machine makes very little noise in its operation.

The Liverpool Copper Market.

During the month of July Chile bars have reached a lower point in Liverpool than they have ever done before—£53 5 s. for good ordinary brands, representing a fall of £2 10 s. per ton from the 1st of July to Aug. 1st. The chief causes of this depression have been the large charters advised for the six weeks—8,700 tons fine; the failure of a special sale on the 15th, at which 1,146 tons were offered at £60, the highest bid being £58 10 s.; the increase in the stocks of Chile copper, and the small deliveries. The English smelters, however, have experienced an unusually active demand, chiefly for India, though at low prices. The arrivals from Chile in August were 3,405 tons, and the deliveries 2,727 tons fine. From other countries the arrivals in Liverpool have been 2,059 tons.

The latest quotations, as given in Jamea Lewis & Sons' monthly report on ores and metals of August 1st, are—Bars, good ordinary brands, £53 5 s.; best brands, £53 10 s. to £53 15 s.; copper ore 10 s. 6 d. to 10 s. 9 d.; regulus, 10 s. 9 d. to 11 s. per unit.

Chile exports to July 27th, for the year, aggregate 34,691 tons fine, against 29,483 tons during the same time in 1878; 29,653 in 1877, and 32,343 tons in 1876.

Stocks of West Coast produce on hand equal 30,454 tons fine, against 29,776 tons on July 1st, against 22,661 tons on August 1st, 1878, when quotations were £61 10 s. In 1875 stocks were only 13,404 tons, and the price £79 per ton. The Board of Trade (Liverpool) returns for the first six months of this year, in fine copper, show imports of ore, regulus, etc., equal to 48,885 tons, and exports of 31,214 tons.

The Alaska fisheries are inexhaustible, and a catch of from 4,000 to 7,000 salmon with one haul of the seine is of common occurrence. Two wealthy San Francisco firms started canneries in Alaska, and last year sent down between 7,000, and 8,000 cases, each containing four dozen one-pound cans.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS

Foundries in Nevada Mines.

EDITORS PRESS:—The wear and tear of machinery in the large crushing mills and heavy hoisting works of the mines, together with the various amalgamating processes and other operations, is necessarily very great; but to send from two to four or five hundred miles for repairs is both expensive and a loss of much valuable time. Hence each important mining district needs a foundry and machine shop if possible. Therefore these enterprises ought to be encouraged by local patronage as far as circumstances permit.

In Tuscarora is one such foundry, small hut to appearances doing excellent work, owned by Messrs. Jack, Dowe & Prout. Fine amalgamating pans of three and a half tons and large retorts we saw being cast, which we judged as well done as any we had anywhere seen. At Paradise Valley we found one still smaller, for the Mount Rose and Willow Creek mines, but it was not in good running order. They were hoping for an improvement. Directly on the railroad the needed work can very well be done at San Francisco, Sacramento or Marysville. Reno, and some other places, more especially to the north and west of there, have largely patronized the Marysville foundry. Mr. Ghorum, Superintendent, where on our spring visit we saw some of the very finest work of the coast, done by the largest and most complete machine shop outside of San Francisco and the Sacramento railroad works.

At Virginia City are the largest foundries in Nevada State, of which the Fulton works on the divide towards Gold Hill is the first in every respect. We saw in this foundry the days were there being prepared the heaviest single casting we were told on the coast, an immense wheel of 15 tons, though one of 17 was soon to be also cast. The work was successfully done.

We never cease to admire the marvelous process of pouring the red liquid mass of iron as easily as so much water, and then the quiet change into the solid fixed form as designed for permanent use. The Creator seems to have arranged all things for man's most convenient manipulations in accordance with his design for usefulness, if only he will study the laws of nature and take advantage of them aright. But in them is found no favor to the ignorant, the willful or the careless.

Near the Fulton foundry are the well managed boiler works of G. E. Belmar, the only steam boiler works we were told east of the Bay, excepting those of the C. P. R. R.

Eureka has two moderate foundries, the largest of which was burned in their great fire, one plainer of \$1,200 value being all that was saved.

A Good Prospecting Stamp Mill.

In Silver City we saw what we believe is the best small prospecting mill we have ever known, a new invention patented by Mr. C. P. Stanchfield. It is a revolving hollow cylinder, through which at right angles to the hollow slip the stamps of suitable weight as the cylinder revolves. This consisted of five stamps, thus practically becoming ten by their revolution to fall alternately on each end. Into the hollow cylinder is forced a constant stream of water, which keeps all sand from entering the sockets in which the stamps slip, and also keeps the crushing quartz wet as needed. The stamps not only crush by dropping, but also grind by slipping after the fall as a necessity from their revolving. The only power needed is three-horse power, where usually upright five stamps take ten-horse power, with no more work done. The whole is easily loaded, and then drawn by a four-horse team to any place for use and immediately set for work again.

Fuel for the Mines.

A difficult problem for Nevada State in the near future is that of the fuel supply for its immense mining enterprises. Its limited good forests along its western line, on the eastern narrow slope of the Sierras, is being rapidly swept away, while through its central portion a stranger would think there is none so little is there to be seen. Virginia City with its immediate vicinity consumes in round numbers some 300,000 cords a year, or at 30 cords per acre, 10,000 acres. This in a few years would lay bare all that portion of the Sierra range in Nevada State. But Virginia City is only a part of the mining regions of Nevada. The Eureka and Richmond mills alone, besides all the different hoisting works at the six or seven mines, use up daily and in round numbers 180 cords, *i. e.*, together 360 cords. This is mostly in the form of charcoal hauled in by teams from many miles away for smelting all their ore. This is about 150,000 cords a year. Tyho has used three-eighths as much, or 50,000 cords.

This will, not long in the future, leave the State without a forest in its territory, except the very slowly-maturing second growth. Already sage brush is being extensively used, but this, too, must fail in time. At Lewis its two mills use mostly this brush for fuel at an expense (for one of the mills), we were told, of \$34 a day by contract for all they might need, though some five cords of wood were also consumed.

At Tuscarora also sage brush was mostly used, though its extensive valley in front is all cleared of this brush for nearly 10 miles away. This second growth comes forward very slowly, taking probably 20 years for maturing. Still, in Tuscarora a large amount of wood has been burned. The Grand Prize even now, at its new hoisting works, alone uses 30 cords of wood a day, at an expense of \$17 per cord on the average. As yet no good coal has been found west of Salt Lake and east of the Sierras, though some poor, unused varieties are found in veins of from two to four feet in width near Elko and Battle Mountain, and Dayton, and a few other places. No petroleum has been found, though searched for.

Water in Nevada Towns.

Most of the towns of Nevada have barely water sufficient for household use, and that of the mines. Few have little or any to spare for irrigation, unless at great cost, which families can ill-afford to meet. Hence towns, such as Tuscarora, which with water in abundance could be made one of the most lovely on earth, has but one green growing spot in it, a little circular inclosure nine feet in diameter, in a low out-of-the-way place of the suburbs. This want of water detracts immensely from the loveliness of all the mining villages of the State.

Virginia City is partly an exception in this respect, since the very costly introduction of water from the Sierra range at an expense of over \$2,000,000. This is done by a large iron pipe across the head of the Washoe valley, descending and then ascending over 700 feet, thus incurring at the lowest point a pressure of some 325 pounds to the square inch. Before this improvement water was sold at the rate of \$2 the week where a boarding house wished eight pails a day. Now it is sold at about 50 cents a week for all needed for use. Still, at this rate only a little is used for irrigation, though the more wealthy have cultivated some very lovely green dooryards, while fine shade trees are beginning to dot the better portion of the city.

At Eureka are four or five green dooryards, and some small trees. At Tybo none except in front of the company's fine dwelling. Water is here sold at five cents the common pailfull. At Belmont there are three really green, pleasant, irrigated dooryards, no others, though for domestic use water is plenty. This is sufficient for an illustration of the whole. We speak not of the towns on the Humboldt, but of the mining towns of the State. These are all thus scarce of water, while the regions around are as dry as dry can be, desolate, barren, rugged, mountainous, grand and worthlessly magnificent as can well be imagined. S. V. B.

THE MANUFACTURE OF VENETIAN GLASS.—Articles in black glass made in Venice are distinguished from all similar products by the intensity of their black color. The question has often and vainly been asked, what special ingredient has been employed to give the glass this color. M. Kayser, a chemist of Nuremberg, in order to discover this, made an analysis of a glass known to have been made in Venice, and compared it with black glass, such as is used in the manufacture of Venice heads. This comparison brought out the fact that manganese is the substance employed to give the black color to glass in which it exists. In fact, while white glass contains only 1.80 of manganic oxide, black glass contains 11.39, and that is the only notable difference that the two analyses present. To confirm this result, M. Kayser melted in a small furnace a mixture of sand and sulphur, in which he introduced 15% of peroxide of manganese. He thus obtained a glass of a deep black color; in very fine threads or thin splinters it was of a somber violet. In one word, it exactly presented, in respect to color, the same properties as genuine black Venetian glass.

MAKING PHOSPHIDE OF HYDROGEN.—In preparing phosphide of hydrogen, or "phosphureted hydrogen," for a lecture experiment, it is common to use potash lye and phosphorus, giving the beautiful smoke-rings when the gas bubbles are ignited. Herr Rosenfeld has lately recommended a simple way of getting the same phenomenon by decomposition of phosphide of calcium with water. A piece of blotting-paper is rolled up to form a tube, and is closed by tying at one end. It is then half filled with powdered phosphide of calcium. In the open end is tied with wire a fine quill with a small opening. The whole is then wound round with wire to prevent lateral escape of the gas. In making the experiment the arrangement is simply placed upon water, care being taken that the quill point dip in the liquid (the quill may be surrounded by a close-fitting glass tube). The water slowly penetrates the blotting-paper, and decomposes the substance enclosed. The phosphide of hydrogen escapes through the quill in bubbles which, on being ignited, give beautiful smoke-rings.

"MANY MICKLES MAKE A MUCKLE."—According to the calculation of Mr. G. T. C. Bartley, an ounce of bread wasted daily in each household in England and Wales is equal to 25,000,000 quatern loaves, the produce of 30,000 acres of wheat, and enough to feast annually 100,000 people. An ounce of meat wasted is equal to 300,000 sheep.

TO BLEACH LINEN.—A teaspoonful of turpentine boiled with white clothes will aid the whitening process. This is due to the formation of hydroxyl.

Montana.

Her Natural Resources—Mineral, Agricultural and Grazing—Varied Fortunes.

Latterly Montana, as a mining country, has been retired to the background, and in this respect hardly met with full appreciation. The causes for this, though varied, have not been peculiar to this Territory, Idaho, and to some extent other of her neighbors, having in like manner been sufferers. Upon the discovery of placers in this region a large population rushed in, and proceeding to work the diggings with the eager energy characteristic of the early placer miner, exhausted the same with great rapidity. For the first eight or ten years following the discovery of gold, business of every kind was active and prosperous in Montana. From almost no white population at all the Territory came to number over 30,000 inhabitants. Thrifty mining camps sprang up everywhere, and several considerable towns were built at eligible sites, some of which have since grown into respectable cities. Attracted by her fine grazing resources, and the markets that existed for beef and the products of the dairy, stockmen from Nevada and Texas drove their herds in by the thousand. Numerous hands of horses were also taken in from California for pack and draft service and the purposes of breeding. Roads and ditches were constructed, fields enclosed and cultivated, saw mills, flour mills, and in due time, some quartz mills and other reduction works were put up; these last coming only after the surface placers had been pretty well depleted.

She Gets a Set-Back and Comes up Again.

With the attempts at working her vein mines, Montana's difficulties began. The gold and silver-bearing ores proved more or less refractory. Labor was high, material of all kinds was costly, and the country without skilled metallurgists and miners. And so the business of working this class of ores failed to meet expectations, and experienced a set-back almost at the start. With this partial failure came a general reaction; trade languished, property depreciated, and a good many people left Montana, which, with all her mineral richness for the time being, passed under a cloud. Latterly this cloud has begun to lift and the prospects of the Territory seem better just now than ever before.

One cause of this improvement is the near approach of a railroad to her borders. In less than a year, the Northern Utah narrow-gauge will have entered Montana, and it will not be long thereafter till it will have been extended to some of her most important mining centers. With the cheapened freights that must ensue, mining, already somewhat stimulated, will receive a great impetus, causing property to appreciate and imparting new life to every other branch of business.

In some respects Montana may justly claim advantages over all her sister Territories. The climate is excellent, considering that the country lies above the 45th parallel. The winters are not severe, nor are the summers extremely hot. There is never much snow in the valleys, though it falls to a great depth on the higher mountains, affording plenty of water for irrigation in the summer, and also a great deal for the propulsion of machinery. While the summers are dry, nearly enough rain falls in the spring and early part of the summer to mature the crops without recourse to the artificial use of water. The natural grasses grow quite plentifully nearly everywhere, and most of the mountains contain more or less timber.

Mines and Mining.

Touching the mining industries and mineral resources of Montana, a correspondent of the New York Tribune writing to that paper under recent date, claims for these a special prominence, admitting at the same time that it is doubtful whether the agricultural, grazing or the mineral resources of the Territory are going to ultimately take the lead. Mines of gold, silver, copper, lead, iron and coal have been discovered, says this writer, in every county, the mineral-bearing territory here exceeding in dimension that of any other western commonwealth. This vast mineral wealth, not segregated in one giant fissure like the Comstock, is distributed in hundreds of veins, many of which are now yielding ore so rich that it pays for transportation to the Eastern States and even to Europe for reduction. The total yield of the precious metals in Montana during the past 16 years has been \$153,000,000—more than that of Colorado, Utah and Idaho combined. About \$147,000,000 of this is in gold, placing Montana only second to California in the production of that metal. Over 20,000 quartz mines have been recorded, and some of the mountain ranges have hardly been the scene of a single vivouac of the prospector.

Montana's Silver Production.

1873.....	\$ 201,300
1874.....	490,766
1875.....	660,000
1876.....	1,132,878
1877.....	1,250,000
1878.....	2,250,000

The total mineral yield in 1878 is placed at \$6,763,000. Over \$1,000,000 were invested in new smelting works, furnaces, mills and other improved appliances, which increase the productive capacity to such an extent that the yield of the mines will be easily increased 25% during 1879. Ores containing from 20%

to 60% copper, unlimited in quantity, are found in several districts. There have been on exhibition at Helena ores from 48 different iron mines or deposits running in value from 25% to 80% iron, and representing every conceivable variety of ore. An iron mountain in Deer Lodge county, larger than the famous deposit of Missouri, averages 30% of that metal. Coal beds lie within three miles, and an iron furnace will be built this season. Prof. Hayden and others estimate that from 50,000 to 65,000 square miles of Montana's area are underlaid with coal. Several of the measures are yielding an excellent quality of fuel. Lead ores averaging 75% lead and a proportion of silver are frequent.

Importance of Testing Water Pipes and Pipe Joints.

Testing pipes and pipe joints in the open trenches in which they are laid, forms the subject of a "selected paper" in Vol. 56 of the "Proceedings of the Institution of Civil Engineers," by Mr. M. M. Paterson. The importance and difficulty of securing good pipe conduits has frequently been referred to by hydraulic engineers in discussions upon water works, and it is admitted that a large amount of silent and invisible leakage from the mains accompanies most systems of water supply. Among instances of the evil effects of leaky mains may be cited Liverpool, where the consumption of 117,425 persons was reduced from 32.12 gallons to 15.97 gallons per head per day by the repair of leaks, discovered by the waste water meter system adopted by Mr. Deacon; Vienna, where a special commission was appointed to report upon the failures in the main line of conduit to that city; and Lewes, in Sussex, where an outbreak of fever has been traced to this cause among others. In laying the pipes for the Ossett water works, the whole of the pipes were tested in lengths of from 60 to 500 yards, after jointing in the trench. From the record of these tests an analytical table was drawn up, whence is obtained the following summary, showing the percentage of failures of the aggregate of all sizes: Total joints tested, 7,763; number of failures, 244; percentage, 3.14. Total straight pipes tested, 7,249; number of failures, 104; percentage, 1.43. Total special pipes tested, 514; number of failures, 50; percentage, 9.72. These results are, so far as the pipes are concerned, solely attributable to concealed defects in the castings, discoverable only after calking and while under pressure. The author's conclusions are: 1. That the usual mode of laying cast-iron socketed pipes without testing after jointing, and in the open trenches, does not give sufficient security against leakage. 2. That by such testing the desired security may, in most cases, if not in all, be obtained at no great inconvenience or cost. 3. That all pipes, special pipes included, should, if possible, be tested before leaving the foundry. 4. That the value of the principle of casting pipes with the socket downward is confirmed, although it affords no absolute security against defective sockets. 5. That systematic testing after jointing will tend to improve the quality of both castings and joints, the cost of each failure being thus largely increased, and falling upon the contractor at fault. 6. That the public will be further secured against accidents to pipe conduits, with their attendant evils, viz., the cost of repairs, the loss of water, the interruption of supply, and the indraft of gas or other foul air at leaky points when the pipes are empty.

CLEANING AND TINNING METAL PLATES.—For the more speedy and economic coating of metal plates with grease and metal Mr. W. Knight, of Pontypridd, proposes to employ revolving or otherwise moving flat surfaces or rings, made of wood, metal, or other suitable material, which may be uncovered or covered with a hard or soft material, according to the special requirements of the operation. He supplies palm oil or other kind of grease to such surfaces or rings by means of hollow spindles or hoppers; he passes the plates to be treated through such surfaces or rings by any suitable means for the purpose of the greasing process, which being concluded they are conveyed through metal and grease to be coated with tin or other metal contained in a corresponding pot. After leaving the pot, he carries the plates through moving or stationary brushes. After passing through the brushing operation, he then carries the plates through metal, and then through grease into the finishing rolls. He puts the required pressure on the finishing rolls by means of spring balances attached to the end of levers, cranked or otherwise. He also employs machines fitted with the before-mentioned moving flat surfaces and rings, as cleaning machines, and proposes using bran or pollard mixed with powdered fuller's earth, the plates being placed in boxes containing fuller's earth working on axles with side openings or doors, the plates remaining a short time in contact with the material before being passed to the machine.

ANTIQUITY OF MAN.—The doctrine that man had existed on the earth only about 6,000 years had been so long believed and so universally accepted that there seemed to be little or no disposition to call its truth in question. But this quiescence has been rudely startled by the announcement that recent research has brought to light human relics and fossils that demand for their explanation a lapse of time amounting, according to some, to tens of thousands, and, according to others, to hundreds of thousands of years.

MECHANICAL PROGRESS.

The Westinghouse Brake.

A very interesting and important set of experiments were carried out some time since on the Northeastern railway with air engines and trains of carriages which have recently been fitted with the Westinghouse automatic brake. They were conducted by Capt. Douglas Galton, C. B., F. R. S., under the personal direction of Mr. T. E. Harrison, the Engineer-in-Chief of the Northeastern railway.

The brake apparatus fitted to the train in question is similar in general principle to the most recent applications on other lines. Slight modifications, however, have been introduced into the details, as suggested by matured experience. For instance, the brake pipes are one inch in diameter internally, without bends at the ends of the carriages, instead of being three-fourth-inch pipes with bends, as formerly. The hose couplings have valves so arranged that when united there is a free passage for the compressed air. When they are disconnected in the ordinary way the valves are closed, but when the couplings are drawn apart by the accidental separation of the train the valves are left open. Formerly cocks were used in the brake pipes at each end of the carriages, and these had to be opened or closed by a movement independently of the act of uniting the couplings, so that the working here is greatly simplified. In the next place each carriage is now fitted (although at present only experimentally) with a friction or reducing valve, which is operated by the friction of one of the brake blocks. This valve is an automatic apparatus, the function of which is to prevent the wheels skidding, which is always objectionable in braking a train. In practice, when the pressure upon the brake blocks reaches the point at which skidding commences, this friction valve comes into operation, and at once reduces the pressure below that point. It allows the wheels to revolve, but retains upon them the maximum amount of brake power. The special novelty upon the present occasion was a modified form of triple valve, which is placed on every carriage. By the aid of these valves the driver can admit any degree of pressure into the brake cylinders. So far as present experience has gone, the new form of valve overcomes all the difficulties hitherto encountered in this portion of the apparatus.

Another feature now introduced for the first time is a pressure regulator, which is placed on the engine. This regulator perfectly controls the maximum pressure in the air-reservoir by stopping the working of the pump at any pressure at which it—the regulator—may be set. If, for instance, a pressure of 50 pounds, and no more, is required in the air reservoir, then the regulator, being so set, stops the pump when the pressure has reached 50 pounds.

The only other modification calling for notice is that respecting the leakage valve, which has been superseded by a short groove in the brake cylinder. This groove allows any slight discharge of air from the triple valve, caused by a leak in the main pipe, to escape. If, however, the air enters rapidly, as for setting the brakes, the piston moves past the groove and prevents any escape of air.—*Iron.*

A New Stone Dressing Machine.

Messrs. Brearley & Marsden have patented in England a new machine for dressing stone, the mode of working which is very simple. The stone is operated on its whole width by a number of cutters, which strike it in an oblique direction, the motion at these points being one of scooping, in fact the motion of the cutters is an exact imitation of the movement of a mason's chisel when worked by hand. Motion is given to these cutters by means of a number of eccentrics cast on the driving shaft and carried on a strong cast-iron frame, which can be raised or lowered by means of a hand wheel and screws to regulate the depth of cut. Each eccentric is set at a different center on the driving shaft, so that only one cutter strikes the stone at the same time, thus causing greater regularity of working and economy of power; six horsepower, we understand, being quite sufficient for driving the machine. The cutters used either for molding or plain work consist simply of small plates of steel about 3/4-inch thick, whilst in plain work of most kinds of stone thin sheets of steel 1-16 inch thick can be used. These require very little sharpening, the thinnest cutters practically sharpening themselves, as one edge becomes sharp whilst the other is wearing, all that is then necessary being to turn the cutter round, and for cutting moldings it is only necessary to use cutters of the shape required to make the mold. In order to produce the best class of work from rough hewn stone at the quickest rate, some of the machines are made with a patent arrangement, by which two sets of tools can be worked from the same eccentrics, and as one set is brought to operate on the stone, the other set is moved out of the way. In this apparatus the frame which carries the eccentrics is made in the form of a quadrant, which can be swung from the center of the eccentric shaft, into any position, by means of a hand-wheel working a pinion in a toothed segment, one set of cutters being carried on the point of radius of the quadrant, and the other on the back radius, so that when the quadrant is swung into such a

position that the cutters in the back radius work on the stone, those on the front radius are at the same time raised clear of the work. Excellent specimens of the work done by the machine are exhibited. One machine of the size to take in four feet wide, and nine feet long is capable of working as much as 400 superficial flags or landing per day, at a cost of less than one-fourth of which it would be if worked by hand.

Compound Locomotive Engines.

M. Anatole Mallet, a well-known French railway engineer, has shown practically that the compound system is peculiarly advantageous with locomotives, for which steam jacketing cannot perform the good work it does with stationary engines, which may be supplied with delicate cut-off gears for high expansion, none of which have been able to stand the test of practical working when applied to locomotives. The compound system admits of using in each cylinder only moderate degrees of expansion, such as are very readily obtained with single slide valves, worked by the ordinary kinds of link motion. M. Mallet designed a locomotive differing as little as possible from the ordinary type, the small and large cylinder being connected by a special contrivance, coaling the engine to work at any time with direct admission and exhaust to both cylinders. They were first tried on the Biarritz and Bayonne railroad with six-wheeled tank engines. The consumption of coal for the average of one year's working was 0.206 pounds per mile per ton. An improvement was introduced in the engines built for the Hainville and Triaucourt narrow-gauge road, the object of which was to prevent the considerable drop of pressure occurring between the two cylinders, owing to the capacity of the intermediate chamber or receiver. It was necessary also to provide an arrangement for cutting off to best advantage in both cylinders, instead of making the expansion equal in both. M. Mallet has also added a self-acting reducing valve, with the purpose of keeping the power equal on both sides of the engine, and of preventing the total pressure on the area of the large piston, replacing a smaller one in remodeled engines, from endangering the working parts retained and originally designed for a given pressure only. In compounding existing engines, M. Mallet generally retains one of the original cylinders as the high-pressure cylinder, and replaces the other by a new one of larger dimensions for expanding.

NEW ELECTRO-MAGNETIC MOTOR.—*La Lumiere Electrique* says that M. Marcel Deprez has succeeded in devising an electro-magnetic motor capable of doing useful work in many industrial applications. Deprez's apparatus is barely eight inches long by less than six inches in breadth. It weighs about six and one-half pounds, and can supply a power of nearly eight-foot pounds per second with five Bunsen elements. This is considered an extraordinary result, and one which could scarcely have been anticipated a few years ago. Under these conditions sewing machines may be worked by electricity without any cumbersome apparatus. This ingenious system consists of a horse-shoe magnet of eight plates, five and three-quarter inches in length, between the poles of which is introduced a Siemens armature, acted upon by the magnet over a length of two and three-quarter inches. The electro-magnetic armature, instead of being placed transversely to the magnet, is arranged longitudinally and parallel to it. Under these conditions the magnetic power is found to be considerably augmented. The axis of the electro-magnet is parallel to the coils of wire in the magnetizing helix, and, consequently, to the arms of the magnet. At one end it carries a reversing commutator, and at the other end it is provided with a pinion which gears into a wheel, of which the diameter is 30 times greater. When the apparatus is properly regulated, the armature makes 90 revolutions per second, and, consequently, the wheel which it acts upon makes three revolutions. It is upon the axle of this wheel that are fixed the pulleys transmitting the movement, and by which the engine is caused to work either a sewing machine or any other apparatus that is to be set in motion.

THE NEW TELEPHONE.—The French government has granted the first concession ever made by it for running telephonic wires to Mr. Frederick A. Gower, of Providence, R. I. Hitherto the telephone has not been used in France, the commissioners appointed by the Telegraph Department to examine existing systems not being satisfied with them. The currents in Gower's telephone are generated by a magnet strong enough to allow a battery to be dispensed with. The increased power is gained by abandoning the horse-shoe form. It is shaped in a half-circle, with two arms bent into the center, where they nearly touch each other. Signaling is effected by blowing through a reed like that of a parlor-organ, this reed being cased in a tube and passing under the diaphragm, near the pole of the magnet. Superfluous vibration, the cause of indistinctness, is thus dispensed with. The vibration in the reed sets up an intense vibration in the diaphragm, which transmits a magneto-electric current to the receiver, producing a clear, loud note. The speaking-tube is then taken up, and the voice is heard distinctly. The diaphragm and magnet are incased in a small metal box, from which the reed emerges. A company is forming in Paris to carry out the invention. Applications for its use are coming in from all quarters.

SCIENTIFIC PROGRESS.

The Manufacture of Soda, Potash, Etc.

Of late years a great change has taken place in the mode of producing sodas and potash. Not so very long ago the alkaline salt potash was obtained principally from refuse and worthless materials. Thistles, potato stalks, and such like were burnt, and the salt contained in the ashes from them was dissolved by the admixture of water. The water being allowed to evaporate, what remained was potash. When to this was added nitric acid we obtained saltpeter. The latter was frequently found in minerals along with nitric acid, but still more, was formerly made from the dunghill, where the refuse being left to rot in the open air the liquor from it was filtered and crystallized. But now potash is made from waste salts, and in Germany there are large manufactories for its production from such, whilst it is also made from chloride of potassium. At Stassfurt and Leopoldshall the potash is produced from the variegated bitter salts, which are found lying above the rock salt. In addition to the ordinary purpose for which potash is used, it is made so as to become a good manure, being mixed with sulphate of magnesia and salt. The manufacture in Germany finds employment for some thousands of persons in the works and the mines connected with them. Another alkaline salt, sal-ammoniac, frequently used by ladies in their smelling bottles, was formerly obtained from the refuse of the stable, being formed by the union of two aeriform bodies, carbonic acid gas and ammoniacal gas, the result of animal and vegetable matter in a state of putrefaction. But it is now made from salt similar to potash, and manufactured rather extensively in Germany, as well as alum, which is used for so many purposes. When reduced with common salt to an impalpable powder, and mixed with spirits of wine, a quantity of it put on the hand will make the latter impervious against a red-hot poker. Soda is now largely manufactured in Germany in connection with potash. There are several processes that have been tried from time to time, and chloride of soda has been turned into soda by bi-carbonate of ammonia, but the process known as Cehlan's is that most generally adopted, being by a succession of reactions. From the refuse left, and in the manufacture of soda, we have hyposulphide of soda. The lye that is left from the soda contains a good deal of sulphide of calcium, and having added to it sulphate of soda there is sulphate of lime; which, being taken away, leaves the hyposulphide of soda brought to perfection by crystallization.

With respect to the great European salt deposits, the theory is that they owe their origin entirely to the elevation of the mountain chains with which they are so intimately connected, and during which small valleys and ravines would be cut off from connection with the sea by ridges of land, and would form salt lakes and lagoons. In England there are extensive deposits of salt and brine springs, those of the latter, in Cheshire, are mentioned in the Domesday Book. Camden remarks, with respect to one of them, that there was a stair about it, down which half-naked men went to draw the brine in leathern buckets, and then carried it to the wick houses. There does not appear to be any reason why the brine, or at least some of it, found in our English salt mines should be capable of producing the same potashes and sodas as are manufactured so successfully and profitably in Germany. The system adopted of using the rock forming the upper parts of rock salt beds seems to be simple, and the same as used to be adopted by Hermann and others in preparing the ordinary leach-brine of saltworks. However, we are not aware of there being any soda and potash manufactory in this country, although it is an important industry abroad.

Gas-lit Buoys.

That the huoyes which mark channels and wrecks are sometimes destroyed or displaced by vessels running along the coast on dark nights is well known. After two trials of lighted huoyes, therefore, the Trinity Board has resolved upon sending a huoy, of which the lantern can be kept continuously burning, to a station off Dundee. The first of those trials took place in August last at the Trinity wharf, when the light lasted uninterruptedly for 23 days. Water was pumped upon it from a steam engine, to see what would be the effect of the shock and drenching, and no harm was done. The huoy was then sent down to the Nore, and there burned steadily for 24 days. The same huoy has now left London for its appointed place at Dundee. Provision has been made for keeping it alight without any interference for 34 days.

It is a huoy of most awkward construction, but this does not lessen its usefulness, and there are being more skillfully made to receive the same illuminating apparatus. This is a modification of what is known as Pintsch's compressed gas system, which was first brought out in Germany. It is proposed to make the huoy itself the recipient for containing the compressed gas, with its regulator (which is one of the most important parts of the invention), and the lantern at the top of a short conducting tube. A huoy of ordinary size will burn about

three mouths night and day, with only one filling, and the light is visible at a distance of about four miles. There is, however, in existence an electric lighting apparatus which might be employed, so that the light could be extinguished at sunrise and restored at sunset, giving, of course, a much longer duration to the working of the buoy.

Utilizing Iron and Steel Shearings.

Thin shearings, or pieces of iron and steel—such, for example, as the scrap from cutting iron sheets for tin-making, and from various other operations in which thin sheet iron or steel is employed—are very frequently reworked with other metals, either in the puddling furnace or in the refining furnace. In some cases the scrap is placed loose in the puddling or refining furnace, but more commonly it is made into bundles. In any case the binding only serves to keep the material together while heating up, for the bundle then falls apart, allowing the metal to mix with the remainder of the charge upon the bed or hearth of the furnaces. There is much loss in this process of reworking, 30 cwt. of this scrap not producing more than a ton of manufactured metal. According to the invention of Mr. J. H. Rodgers, of Llandly, England, the shearings or waste pieces of thin iron or steel are compacted together into masses or blocks, and these are placed in a re-heating furnace, and when heated to a proper temperature, are consolidated under a steam hammer, or in any other convenient way. In this manner he can obtain a ton of manufactured metal from 23 cwt. of shearings. In order to form the shearings or pieces of iron or steel into masses or blocks ready for heating, he places them in a box or mold, and with a steam press or other suitable machine he presses the contents of the box or mold until a compact block is obtained. The mass thus compacted is withdrawn from the box by an opening provided for the purpose, and which is closed by a door while the material is being molded. The compacting of the scraps is performed in a cylinder or mold, wherein they can be compressed by a kind of steam hammer. To discharge the molded mass, the box is opened and by means of a bar inserted at a suitable hole it is forced out in a condition to go into the re-heating furnace. In the furnace, and in the subsequent hammering, the blocks or masses are treated in the same way as piles or blooms.—*Phila. Trade Jour.*

SMOKE OF AN ELECTRIC LAMP.—Prof. B. S. Proctor, to whom was referred the sooty deposit on the inside of a glass globe used with an electric lamp, says, in the *Chemical News*: "Under the microscope the smoky deposit on the glass showed numerous bright globules, no doubt platinum, and more minute particles of dark matter, nebulous under a 1/2-inch objective. A fragment of the glass exposed to an oxidizing heat, the deposit partially disappeared, still leaving the glass slightly darkened. The platinum support—which had also a coating of dark sublimate at a little distance above and below the carbon pencil, but not in immediate juxtaposition with it—was next examined by exposing to the blowpipe flame the unsmoked portion, so that the conducted heat might act upon the deposit without the fear of the blast carrying away the matter, which was very loosely attached. In this way the deposit was burnt off without the mechanical action of the blast, the heat to which it had been subjected being that of dull redness. A piece of the glass was then treated with aqua regia for several days. The deposit was diminished, but far from being entirely dissolved; the solution gave a blue reaction with yellow prussiate of potash, and no coloration with tannin till aided by vapor of carbonate of ammonia, when the usual purple color of ferric tannate was developed. There is thus evidence of the deposit containing platinum, carbon and iron. Probably the scattering of platinum globules might result from the disruptive discharge which took place at the moment of the lamp breaking down."

PREHISTORIC STONE IMPLEMENTS.—It has been supposed that the stone implements, especially the flint spears and arrow-heads used by the prehistoric inhabitants of Europe and America, were made by chipping off fragments from a piece of suitable size with a rude stone hammer. Mr. Cushing, curator of the Anthropological Museum of the Smithsonian Institution, who has made a very interesting experimental study of aboriginal processes of manufacture, found it impossible, by using the rude implements that were within the reach of the ancient manufacturers, to imitate, by chipping with a stone hammer, the finer and more delicate specimens of Indian arrow-heads. He accidentally made the interesting observation, that small fragments could be broken off from a piece of flint with much greater precision and certainty by pressure with a pointed rod of bone or horn than by blow with a stone hammer. Mr. Cushing was enabled in this manner to "flake" spear and arrow-heads into the most delicate and fragile shapes, with a degree of certainty that renders it almost equivalent to demonstration that this was the mode adopted by the aborigines for working flints before the introduction of iron.

NICKEL.—It is known that nickel, like iron, is magnetic, sufficiently ductile to be forged and drawn into wire. Its point of fusion is very high, and if melted in the proper kind of crucible it yields a homogeneous regulus of a silvery whiteness containing carbon.

The Mining Share Market.

"Slack and sluggish" are the stock words which have characterized the market for the past week. Beginning at a slight rise, the market lost its grip and fell again, remaining at the same level up to the present time of writing. There have not been any great "opportunities" for speculation. Comstock seems to be flat on its back, although there are considerable expectations. Too much deferred hope sickens the public. After all, our mining stocks may now be considered as approaching their normal condition, and to rise to any great degree will involve exciting news which buyers and sellers do not expect. The condition of things on the Comstock, viz.: water, is a striking illustration of the quality of some of the stock, and, as the public have been often flooded with watered stock, so now the favorite element of the manipulators has taken possession of their mines—a just retribution. In our opinion the time has gone by for sudden and great fluctuations in stocks, and reasonable profits obtained by ordinary fluctuations must alone be expected. We would rejoice if the evils of stock speculation had effected their own cure.

Bodie might stand a rise. The out-put of the mine and the prospects would justify it. But the stock has not yet gone a-begging, and cannot be had at ruling prices on every street corner. All the stocks seem to feel the depression of the times, and, like sugar and other things, come down to bedrock prices. Although we might be correct in saying that the caution exercised in purchasing has forced holders into the condition of temporary bears against their will.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Hillside, August 15th, \$4,600; Alexander, August 15th, \$7,205.33; Bodie Con., August 15th, \$12,500; Leopold, August 19th, \$4,000; Hillside, August 18th, \$4,400; Belle Isle, August 18th, \$21,000; Independence, August 18th, \$4,300; Northern Belle, August 16th, \$4,242.07.

CENTRAL STEAM SUPPLY.—The system of supplying steam for all economical and household purposes, as gas is, from a central manufactory, seems to be gaining headway in the Eastern States. The system has been introduced in Detroit, Michigan, where 10 miles of pipes are already laid, and 800 horse-power furnished. Other cities are introducing it. The loss by condensation is averted by junction boxes placed at every 200 feet of pipe. The pipe has an external non-conducting covering of hair felt, and is enclosed in a wooden box. At Springfield, Massachusetts, the system is said to be paying 17% on its cost in the first six months of its use. The practical working of this new feature of domestic and industrial economy seems to be well demonstrated. It has been tried in a small way in nearly every large city. The only new feature about it is its wholesale character. While much doubt has been expressed as to the impossibility of preventing the condensation of steam through such a long system of pipes, the theory is that it cannot be done, while practically it is done every day.

In San Francisco half dollars are quoted at 99 1/2 buying, 99 1/2 selling; trade dollars, 97 buying, 98 selling; Mexican dollars, 98 buying, 98 1/2 selling.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ITEMS.—Dispatch, Aug. 16: A very flattering prospect has been struck in the north drift of the Moore mine, at the depth of 150 ft. Instead of a six or eight-inch vein, they now have a well-defined ledge four ft wide, the rock of which looks very rich. Rock enough is being taken to the mill to keep the mill in constant operation. The large square timbers and other necessary lumber for the Coney holding works are now being hauled to the mine from Brandon's mill, and the grading for the structure is under full headway. Mining operations at Butte basin are progressing favorably. The shaft is down over 30 ft with no gravel in sight. The flow of water is considerable, and powerful pumping machinery is required to keep it down. It is hardly expected to strike pay dirt before a depth of 150 ft is attained.

FRESNO.

ITEMS.—Expositor, Aug. 20: The new mining district recently organized by Tadlock, Collins and others, and named Fresno Mining district, is in the slate range, and contains a number of well-defined ledges, the value of which are yet to be determined by prospecting. Mr. Collins informs us that the principal ledges are found near the western base of Mount Goddard. The three principal ledges run parallel with each other, and are traceable for several miles. The ore carries gold and silver. Below where the ledge crosses a ravine, one of the parties scraped together some earth and gravel, and on panning it out numerous particles of gold were found.

STANFORD GILB MIX.—This mine is situated high up on the western side of Spangled Gold gulch, two miles from where the stream which flows at the foot of the ridge empties into the Fresno river. The tunnel and cut follow the vein 250 ft into the mountain—the cut being 70 ft and the tunnel 180 ft long. At the breast of the tunnel the ledge shows plainly, cutting across the tunnel at a depth of about 125 ft from the surface. It is here four ft wide. The general dip of the vein is about 55°. Some very rich rock is being taken out of the shaft. The vein has been traced one and one-half miles. The rock yielded about 50 per ton.

INYO.

MONROE.—Independent, Aug. 16: At south drift, 300-ft point, run seven ft; drift from winze, 300-ft point, 14 ft; drift from 300-ft point, 15 ft; crosscut from drift, 1000-ft point, 22 ft; upraise at 1100-ft drift raised one ft; drift from upraise, 1100-ft point, 17 ft. Total length of south drift at 300-ft point, 137 ft; drift from winze, 63 ft; 300-ft drift, 112 ft; crosscut at 1000-ft point, 97 ft; upraise at 1100-ft point, 30 ft; drift from raise 17 ft; drift from winze, 300-ft point, 14 ft. The ledge is now five ft wide, and is looking very well. They have upraised on this ledge 80 ft. There is about six ft of good ore in this upraise at present writing. The west crosscut, 300 level, is now in a distance of 40 ft, in good blasting rock. The West Standard ledge in the slope is looking about the same as last report; the ore is 10 ft wide and is as rich as usual. In the south drift, 550 level, the etopos are being panned; the ledge is 12 ft wide, of very fine good ore. The ledge in the Gildea slope is three and one-half ft wide, of good milling ore.

WACO STAR.—This ledge is located about four miles northerly from the Brown Monster mill, on the western face of the Inyo range. It shows an ore body of full seven ft in width, assaying from \$22.50 to \$340 per ton, gold and silver combined. The ledge is traceable for over a mile in length.

MONO.

STANDARD.—News, Aug. 17: The north drift, 385 level, is in 325 ft, and the ledge in the drift is three ft wide, of good ore. In the slope the ledge is from 10 to 20 ft wide, of very fine ore. The winze in the west crosscut, 550 level, is now down 35 ft. The ledge is now five ft wide, and is looking very well. They have upraised on this ledge 80 ft. There is about six ft of good ore in this upraise at present writing. The west crosscut, 300 level, is now in a distance of 40 ft, in good blasting rock. The West Standard ledge in the slope is looking about the same as last report; the ore is 10 ft wide and is as rich as usual. In the south drift, 550 level, the etopos are being panned; the ledge is 12 ft wide, of very fine good ore. The ledge in the Gildea slope is three and one-half ft wide, of good milling ore.

BOOKER.—Shaft sunk and timbered to a depth of 400 ft. Engaged cutting out a station, preparatory to drifting, which will be commenced this week.

SOUTH STANFORD.—During the past week the drift from the west crosscut, 450 level, has been advanced 10 ft, with out much change in the character of the vein. In the drift north from the shaft 11 ft has been made. Work has been commenced at the 200 level, cutting out and enlarging the station to receive a tank of 10,000 gallons capacity.

UNIVERSITY.—Three-compartment new shaft now down 73 ft, and still sinking. In the east side of the shaft at the bottom the ledge makes its appearance and shows a fine character of quartz. The whole width of the shaft is in ledge matter of fair quality, all of which prospects in gold.

MARYLAND CON.—New double-compartment shaft now down 70 ft, showing many stringers of quartz coming in from the west.

VORTEX.—Sinking the winze on the 200 level is still making favorable progress. The ledge in the bottom is two and one-half ft wide, of good ore, formation favorable and looking well. The winze has now attained a depth of 40 ft. It is the intention to continue sinking until connection is made with the west crosscut, now in progress from the Oseola tunnel, owned by the Syndicate company. Connection will be made at a depth of 70 ft. When connection is made, drifts north and south will be started on ledge, and stopping the ore for milling purposes commenced.

ORO.—The bottom of the shaft shows well in mineral, and gold has been found in the rock.

GOODSHAW.—The winze from No. 2 vein is down 50 ft. The formation looks remarkably favorable in the bottom. The south drift on vein No. 2 has been advanced 30 ft.

SOUTH BELVER.—Still continuing work on the 300 level, sinking the winze to the ledge. Ledge in face of drift looking well, three ft wide, all good ore. Winze No. 2 now down 50 ft; ledge in the bottom two and one-half ft wide, showing good ore. The west crosscut on the 420 level advanced 10 ft during the past week, making a total length of 33 ft; ground of a favorable character; have cut several stringers of good ore; indications favorable for cutting the ledge at any moment.

SCURRY.—The north drift, 200 level, has been extended since last report nine ft; total length, 327 ft. The ledge is 15 inches wide. East crosscut from this drift is in 216 ft; progress since last report, 10 ft. The rock in the face is very hard. North drift, 300 level, has been advanced during the week 30 ft; total length, 352 ft. The ledge is three ft wide of fine-looking quartz. South drift, same level, is in 276 ft; progress since last report, 29 ft. The ledge is two and one-half ft wide.

NOONDAY AND NORTH NOONDAY.—The combination shaft is now down 260 ft, and is passing through material of a most favorable character. The west crosscut is being extended through fine vein formation and well-defined bodies of quartz.

BONNIE TEXAS.—The tunnel is now in 1,120 ft, with favorable formation for striking another ledge. The rock is blue porphyry stained with iron, which is a favorable indication of the near presence of ore. The south drift is 75 ft from the main tunnel, following the vein encountered at 900 ft the entire distance, and has about 18 inches of fine quartz between the walls. Air continues good, and men can now work with comfort anywhere in the tunnel.

BULWER.—The south drift, 380 level, has been extended since last report 12 ft; total length, 157 ft. The ledge is two and one-half ft wide of good ore. The west crosscut from this drift is in 30 ft in fair blasting ground. The winze on the Ralston ledge has reached a depth of 27 ft, the ledge two and one-third ft wide of fine ore.

SOUTH BELVER.—Shaft has attained a depth of 150 ft, and are now engaged cutting out station at the bottom of shaft.

SOUTH NOONDAY. Shaft down 65 ft, and drifting north and south on the ledge. The prospects are flattering in the extreme for a pay vein of ore similar to that found in the Noonday further north.

NEVADA.

ORIENTAL.—Transcript, Aug. 16: The Oriental gold mining company expect to have their new mill in operation by the 20th of this month. Over 800 tons of rich ore is now in the ore house ready for crushing.

DEWEE.—The channel in this mine has been opened up over 100 ft, and the west rimrock at yet to be developed. The average depth of the pay gravel is eight ft. Eighty men are now at work, and on the 1st of September 40 or 50 additional will be employed and 500 tons of gravel per day will then be raised. The gravel-washing machine to be put on trial will be ready to start up in about two weeks. It has a capacity of 150 tons per day.

For 10 days past a force of men have been employed in cleaning out the tunnel of the Alice Bell and Lone Star ledges on the Murchie mining company's property. Those leads are to be thoroughly prospected this fall, and the chances are good that holding works will be erected on them before many months elapse. When the Murchie brothers were mining on the Alice Bell and Lone Star they took out considerable rich ore, and it is the belief of many acquainted with the claim that they are better ledges than the Big Blue, which is now being so extensively developed.

ITEMS.—Herald, Aug. 16: Day before yesterday three-quarters of a ton of quartz from the neighborhood of Columbia Hill, was crushed at Keith's mill, and yielded at the rate of \$10 per ton. The lead is over four ft thick and favorably situated. Lowell Hill appears to be in a more prosperous condition than the others. About 75 men are employed drifting in the various claims, and about \$5,000 paid for labor monthly.

PLUMAS.

BLISS GRAVEL.—Plumas National, Aug. 10: The owners of this mine have sunk a shaft to the depth of 90 ft, and drift on the level from it about 400 ft, demonstrating that they were not low enough to reach the bottom of the channel. The hoisting and pumping is all done by water-power, and the loaded cars come from the drift, and raising on the cargo to the surface, are dumped within a few feet of the mouth of the shaft. The gravel on the rim or pitch where they "lost bottom" was very rich, paying from \$2 to \$3 to the carload. The work has to be done again, however, as it will be necessary to sink the shaft 50 or 60 ft deeper, and then run a new tunnel, which will tap the channel low enough to bottom it. Arrangements are now being perfected for this, and we think it safe to say that work on the new tunnel will soon be started. The mine is situated almost on the bank of the Middle Fork in the Willow Creek and Nelson Point country. The hydraulic claim near the same place shows a splendid channel of pay dirt. The bank grows deeper as the work progresses, and at present is probably 90 ft, clear gravel; not a particle of pipe clay, and we are told that it prospects "from the bedrock to the grass-roots."

SACRAMENTO.

FOLSON.—Telegraph, Aug. 10: A number of Portuguese are mining on the opposite side of the American River, for a few days past have been making sluice boxes for the purpose of carrying the tailings from their claims to the river.

SIERRA.

ITEMS.—The tunnel of the Planet gravel mining company is now in a distance of over 1,000 ft, and the drift is entirely in gravel, which improves in its prospects as distance is made. Last week the drift was extended 20 ft. The gravel prospects very favorably, but it is not considered that the center of the channel has been reached, as the big boulders which are found in it in adjoining claims are not yet encountered. The Boston Ravine quartz claim is one of the old locations on Massachusetts hill, located on the dipe and angles, and in length about 1,500 ft, running southerly near the dump-pile on the Stockbridge ground to Mary's ravine, emptying into the Volcano. Work has been resumed upon it. Machinery for a mill has been ordered for the Santa Anita mine. This mine is situated on the northwest side of Poorman's creek, about two miles from the town of Washington. Since January 1st, 1879, to date, 335 mining claims have been located and duly recorded. William Talbert's strike on Gold flat is likely to prove a valuable one. He has sunk down to it about 40 ft, and the lead was gradually enlarged, until now at the bottom of the shaft it is two ft thick. The tunnel in the Besie Miller mine, near Washington, has cut the ledge or a part of it, about six ft thick. It is understood that machinery has been ordered and a mill will be erected soon. At the bottom of the incline in the Scadden Flat mine very rich free gold-bearing rock has been struck. The specimens shown are, besides being well speckled over with free gold, heavily charged with sulphurets.

NEVADA.

WASHOE DISTRICT.

UNION CON.—Gold Hill News, Aug. 20: The drift east on this level toward the Union Con. mine has been extended 100 ft from the main north drift. There has been a slight increase of water in this drift. The joint Mexican crosscut west on the 2000 level is passing through a soft vein formation carrying streaks of quartz and clay; total length, 30 ft. Of late the joint Mexican winze from this level has encountered an increased flow of water, and a donkey pump has been ordered to handle the water. The winze has been worked with in the raise from the 2300 level (Sierra Nevada 2200 level) during the week, and also with sinking the winze from this level; and nothing has been done in either place since last report. On the 2400 level (Sierra Nevada 2300 level) the diamond drill running 2 1/2' west of south from the Sierra Nevada incline, and on a depression of one foot in ten, have developed a continuation of fair grade ore, extending as far as the drill has penetrated. This, together with the developments made by the drill when run at an angle of 45° further west, shows a good body of ore in the mine on this level.

OPHIR.—The 2100 level has been reached on the incline and the station set put in. The material at this point is most promising. On the 2200 level the north drift is making fine progress; its face is a fine vein formation showing streaks of clay and quartz, and 100 ft north of the main east drift. The west crosscut, 2100 level, from the end of the drift north from No. 1 winze is in porphyry showing streaks of rich quartz; total length, 50 ft. The joint Mexican winze from the 2100 level is in hard porphyry, carrying an increased flow of water; total depth, 50 ft. The joint Mexican 2000 level is in soft ground, and yield of 30 tons of rich ore per day.

CON. VIRGINIA.—The joint crosscut, 850 level continues to cut a formation of hard porphyry, carrying some water; total length, 580 ft. No. 2 winze has been reached by the drift on the 1650 level, which is now being enlarged to full size for better ventilation, and the north drift is being extended to the south and east of the old topes on this level and the level below. Crosscut No. 1, 1750 level, continues to penetrate a favorable vein formation showing some ore; total length, 90 ft. On the 2150 level the east crosscut is in 135 ft, the face in favorable rock containing low-grade quartz.

UNION SHAFT. The raise from the Sierra Nevada east drift, 2000 level, has been enlarged to that level, affording increased ventilation to that mine and to the Union. Sinking for the Sierra Nevada 2200 level is being continued. The west drift on the 1000 level to connect with that east in Union ground is in 50 ft and penetrating blasting porphyry.

GOULD & CURRY. The joint east crosscut on the 1700 level is being driven at the rate of five ft per day, through blasting porphyry. At the new joint shaft sinking is going on, the 750 level being at hand. The water con-

tinues to flow copiously, but has of late manifested signs of weakening.

CALIFORNIA.—The drift south from the bottom of the winze, 1950 level, continues in vein matter, showing streaks of ore. The joint west crosscut, 850 level, has its face 580 ft west of the shaft, in hard porphyry, carrying some water.

ALTA.—There is some water at the bottom of the incline below the 1750 level, but a donkey pump was put in place Monday evening, which handles it easily. The south drift, 1750 level, and the north drift on the 1550 level, in Lady Washington ground, are progressing well. Raises are being made in the ore body from the 1550 to the 1450, and from the 1450 to the 1350. The mill is turning out bullion, but the amount yielded has not yet been determined.

MEXICAN. The bottom is in hard porphyry, 50 ft down. The joint Ophir crosscut on the 2000 level is in 45 ft, and passing through a softer formation than at last report. The joint Union crosscut is also in a soft formation carrying quartz and clay; total length, 30 ft. An increased flow of water has rendered it necessary to put a donkey pump in the joint Union winze from this level, sinking now making good progress.

LEVATHIAN. A heavy stringer of quartz, being an offshoot from the main ore vein, some two ft in thickness, was cut through yesterday by the north lateral drift on the 750 level. It gave assays up to \$12 to the ton. The face of the drift is now in hard vein porphyry again, with small streaks of quartz.

ALTA. The shaft has attained a depth of 1,018 ft. The influx of water is strong. The shaft has of late penetrated some very fine-looking vein matter containing low-grade quartz of a promising nature.

BEST & BELCHER. The joint east crosscut, 1700 level, is now in 1,135 ft, the face in hard porphyry which blasts well. The flow of water at the new joint shaft is strong, but manifests signs of weakening.

JAMES.—Crosscuts Nos. 1 and 3 east, 1350 level, are passing through nice quartz which small assays are obtained. The lateral drifts north and south along the west ore chamber and crosscut No. 2 west, are showing epote of nice ore. Sunday the work of opening the 1550 level from the 1550 level of the Alta was commenced.

TRONJAN.—The west crosscut from the northeast drift, third level, is now 60 ft in porphyry and quartz. The raise from the eastern level is passing through porphyry containing streaks of fair ore. It is now up to the 1000 level.

NIAGARA.—The south lateral drift on the 500 level shows an increase of quartz, giving better assays. The north lateral drift, same level, continues in vein porphyry and quartz.

OCCIDENTAL.—The drift north from the bottom of this winze below the lower tunnel is being pushed ahead and is encountering favorable vein matter.

CALIFORNIA.—Sinking the winze from the 1000 to the 1000 level and making good progress. Last evening the depth attained was 277 ft.

BROPHY.—The tunnel is giving increased indications of nearing the ledge, the face being a mixture of clay, quartz and porphyry.

LADY WASHINGTON.—The drift north and south on the 750 level continues in soft vein matter containing low-grade quartz. Work in the drift to get east of the shaft to raise the incline is making good progress. A promising body of quartz is being encountered in the drift west from the south drift 600 level. The north drift on this level continues in quartz and the crosscut east from this is also in quartz giving low assays.

NEW YORK.—The north lateral drift on the 1200 level continues to cut a promising vein of quartz yielding fair assays. The vein bears indications throughout the whole extent explored of making down, and when the 1400 crosscut reaches this portion of the ledge it is believed that important developments will be made.

BELMONT DISTRICT.

BELMONT MINE.—Courier, Aug. 16: The drift running from No. 3 raise north to connect with No. 2 has been extended 17 ft through a vein of quartz 3 1/2 ft in thickness and 2 ft of same rich sulphure ore which will fully \$100 per ton. In No. 4 the ore body above 200 level south of drift is looking fine and continues to get larger as opened up. Taking out about two tons daily of high grade chloride ore.

CORNUCOPIA DISTRICT.

ITEMS.—Gold Hill News, Aug. 10: From F. F. Collier, who has been down from Cornucopia yesterday, we learn that last Saturday the west crosscut on the 300 level of the Leopold struck the main ore body or ledge 193 ft south of the shaft and 50 ft south of what is known as the north ore body. Where the crosscut first struck the vein it was only 4 inches in width, but in running 10 ft south it increased to fully 2 ft of solid ore. Assays from pulp samples from all of the rock taken out in running the distance average \$102.00 in silver. It is expected that the main drift will reach the ledge to-day. The indications are regarded as most favorable for a development in the 300 of the finest and largest body of ore that has ever been discovered in the mine.

COMO DISTRICT.

ITEMS.—Virginia Enterprise, Aug. 15: The Eureka, formerly the Monte Christo, lies near the summit or divide, and is now only 90 ft deep. The ledge is 8 ft wide and nearly all pay ore. They have 70 tons of ore on their dump that will doubtless go \$40 per ton. The old Rapidanock, now divided between the Rapidan and Peerless, has a large, well-defined ledge, and crops out for nearly half a mile. The Cerasus is a promising mine, and is now being worked.

PARADISE DISTRICT.

ITEMS.—Silver State, Aug. 14: Capt. Wright, who has been looking up stock on the Owyhee, near Three Forks, says he discovered several rich and well-defined ledges in that country.

REVELLE DISTRICT.

GILA MINE.—Eureka Sentinel, Aug. 14: This vein in this mine will average about two ft in width, a part of which is very rich, some of it assaying as high as \$1,000 per ton, and it will all probably average \$150. Samples taken by three different parties, some time ago, gave an average of \$100, \$140 and \$115. At or near the end of the south drift a winze has been sunk to the depth of 70 ft on the vein, which carries ore of about the same width and value as the drift above. In the bottom of this winze there is now about eight ft of good ore, with a perfect and regular wall. The ledge, which was badly broken near the surface, has now been recovered, and is found to go down strong and regular. Ore is being stopped and taken to the mill, the latter having been started up on the 30th instant.

REBEL CREEK DISTRICT.

OHIO LEAD.—Silver State, Aug. 18: An assay of a car load of ore from this new ledge sampled at the Utah mill showed \$994.01 in silver and \$13.20 in gold.

ARIZONA.

ITEMS.—Prescott Arizona, Aug. 14: Tiptop mill is running 12 out of every 24 hours. Very rich ore is being raised out of Black Warrior and Silver Prince shafts.

TOMBSTONE.—The Eagle mine shows rich ore in a shallow shaft on a vein of leucite, horn silver, and a little pyrite. The

A Problem in Transmission of Power.

[Abstract from a thesis by CHARLES W. SLACK, College of Mechanics, University of California.]

Wire rope transmission becomes a valuable means of transferring power to long distances when a weaker material will not answer; and the lightness, durability and cheapness of the rope are important factors for the mechanical engineer to consider. For a country like California, having abundance of water power, and where it is often impossible or inconvenient to utilize directly the power near the water, which in manufacturing, such a system of transmission is especially valuable. The principle on which it depends is either to use a large rope working at a low speed, or what is better, a small rope working at a great velocity.

In order to illustrate telodynamic transmission, I will discuss an ideal case: Suppose it is desired to transmit 200-horse power from the vertical shaft of a turbine at A, 250 ft. to a bluff, C, 300 ft., and thence across a valley 1,000 feet, from D to some convenient point, B, for a mill. Required:

(1). The size of the rope necessary to convey the given power.

(2). The diameter of the pulleys.

(3). The length of rope.

(4). The loss of power.

(1). The Size of the Rope.

Allow a velocity of 5,280 ft. per min., or 88 ft. per sec. The work performed is

$$L = P \times V = 550 \times H \text{ P;}$$

From which the resistance, $P = 550 \times 200 \div 88 = 1,250$ lbs. The ratio of the tensions on the driving and driven portions of the rope due to the resistance to slipping is $P_2 \div P_1 = 2$; and since the driving force of the rope is the difference of tensions, $P = P_2 - P_1$ or $P_1 = P$, and $P_2 = 2P$. A rope must be selected which is capable of sustaining the greatest tension, $P_2 = 2P = 2,500$ lbs. According to Mr. A. S. Hallide, an iron wire rope of $2\frac{1}{4}$ in. in circumference, or a diameter of .716 in., is required for a working load of 2,500 lbs.

(2). The Diameter of the Pulleys.

The rope is subjected to two different straining actions. Besides the longitudinal tension due to the work transmitted and the weight of the rope, there are stresses due to the bending of the rope over the pulleys.

Z = diameter of each wire composing the rope.
 p_t = greatest working stress due to the longitudinal tension of the rope.

p_b = corresponding strain due to bending.

T = total longitudinal tension of the rope.

m = number of wires in the rope.

For the stretched wire in passing over a pulley,

$$p = p_b + p_t.$$

The bending moment is given by the well known relation,

$$M = \frac{E W}{R},$$

In which E = modulus of elasticity of the material, W = moment of inertia, and R = radius of the pulley. The strain on the remotest fiber from the neutral axis of the wire due to bending is

$$p_b = \frac{Z M}{2 W}$$

Substituting the above value of M , we have

$$p_b = \frac{Z E}{2 R}$$

The total longitudinal tension is the tension on a unit area multiplied by the sectional area of the rope; or

$$T = p \times \frac{\pi Z^2 m}{4}$$

From which

$$p_t = \frac{T}{\frac{\pi Z^2 m}{4}}$$

Substituting the values of p_b and p_t just deduced in the equation $p = p_b + p_t$, we have

$$p = \frac{T}{\frac{\pi Z^2 m}{4}} \times \frac{Z E}{2 R}$$

Hence

$$T = \frac{\pi Z^2 m}{4} (p - \frac{Z E}{2 R}).$$

To find a value of Z when T is a maximum, place the first differential coefficient of T with reference to Z equal to zero; or

$$2 p Z - \frac{3 Z^2 E}{2 R} = 0; \text{ or}$$

$$Z = R \times \frac{4 p}{3 E}$$

For wrought iron, $p = 24,000$, and $E = 29,000,000$; hence

$$Z = \frac{R}{900}$$

For a rope of .716 inches in diameter $Z = .0699$ inches, very approximately. Therefore, the radius of the pulleys is 5.24 feet for the minimum limit. To be on the safe side, increase R to 7 feet.

(3). The Length of the Rope.

The general equation of the catenary curves formed by the rope is

$$y = \frac{c}{e^{\frac{x}{c}}} - e^{-\frac{x}{c}}$$

in which y and x are the general co-ordinates of points of the curve, c , some constant, and

e , the base of the Napierian system. Develop-

ing $e^{\frac{x}{c}}$ and $e^{-\frac{x}{c}}$ into a simple form, we have

$$e^{\frac{x}{c}} = 1 + \frac{x}{c} + \frac{1}{2} \left(\frac{x}{c}\right)^2 + \frac{1}{2.3} \left(\frac{x}{c}\right)^3 + \text{etc.}$$

and

$$e^{-\frac{x}{c}} = 1 - \frac{x}{c} + \frac{1}{2} \left(\frac{x}{c}\right)^2 - \frac{1}{2.3} \left(\frac{x}{c}\right)^3 + \text{etc.}$$

By this substitution of these values of $e^{\frac{x}{c}}$ and $e^{-\frac{x}{c}}$ in the general equation, and rejecting all the higher powers of $\frac{x}{c}$ which we may do with-

out sensible error provided $\frac{x}{c}$ is a small fraction,

$$\text{we have } y = \frac{x^2}{2c}$$

Thus it is seen that the equation of the catenary is approximately the equation of an inverted parabola referred along its axis to an origin at a distance, c , below the vertex. Hence, the vertex is determined by the equation

$$h + c = \frac{c}{2} \left(\frac{x}{c} + \frac{x}{c} \right)$$

or approximately by

$$h = \frac{a^2}{2c}$$

in which h is the distance of the vertex below the horizontal line connecting the points of suspension.

The general equation for the deflection in terms of l , the length of the curve from one of the points of suspension to the vertex, and c is

$$h + c = \sqrt{l^2 + c^2}$$

from which

$$l = \sqrt{h^2 + 2hc}$$

If K = tension in a tangent at any point of the curve, the equivalent tension are a vertical tension, $V = q l$, and a horizontal tension, $H = q c$; q being the weight per lineal foot of the rope. From the preceding, $K = \sqrt{H^2 + V^2} =$

$$q \sqrt{c^2 + l^2} = q(h + c) = q(b + \frac{a^2}{2h})$$

It is evident that the tension at D is greater

DIAGRAM ILLUSTRATING TELODYNAMIC TRANSMISSION.

than the tension at A ; and if the power was transmitted from A to D direct, the tension at D would be greater than the selected rope could stand with safety. In order to reduce the tension at D as much as possible under the circumstances, place at C , to carry the driving and driven portions of the rope, two parallel guide pulleys, as close together as practicable, in such a manner that their lower rims shall be at the same height as the horizontal pulley at A . Also place two parallel guide pulleys as near as possible to A , so that the rope can lead fair on and from the groove in the rim of the horizontal pulley, and two at D that the rope between C and D may hang perfectly vertical.

Since the tension on the driving and driven ropes changes when the system is in motion, it is evident that the catenary curves will change. We will now consider their positions when the system is at rest and when in motion:

P_0 = tension at A and C when at rest.

P_1 = tension on driven side.

P_2 = tension on driving side.

h_0 and h_2 = corresponding position of the vertex below the horizontal.

$$P_0 = \frac{P_2 + P_1}{2}; \text{ but } P_1 = \frac{P_2}{2}; \text{ hence } P_0 = \frac{3}{2} P_2.$$

$P_2 = 2,500$ lbs; and $q = .86$ lbs. From $P_0 = q(h_0 + \frac{a^2}{2h_0})$, $h_0 = 4.18$ ft. The tension be-

ing the same for the two catenaries between A and C , the vertices will be at the same distance from the horizontal.

When in motion the tension, P_1 , on the driven side, is 1,250 lbs., and $h_1 = 5.40$ ft. $h_0 = \frac{h_1 + h_2}{2}$; whence $h_2 = 2.96$ ft., for the vertex

of the driving catenary.

The length of one of the catenaries, from one of the points of suspension to the vertex, when the system is at rest, is $l = \sqrt{h^2 + 2hc} = \frac{a^2}{2h}$

$1,869.13$ ft., and $l = 125.1$ ft. Hence the total length of rope required for the two catenaries is $4l = 500.4$ ft.

Again let

T = tension at D and B when at rest.

T = tension on driven side.

T = tension on driving side.

M_0 , M_1 and M_2 = corresponding positions of the vertex below the horizontal. The weight of the 300 ft. of rope between C and D is 258 lbs.; consequently $T_2 = 2,758$ lbs., $T_0 = \frac{3}{2} T_2 =$

2,085 lbs., and $c = 2,228.51$ ft., which gives $M_0 = 141.35$ ft.

When in motion, the tension on the driven side is 1,508 lbs., and $M_1 = 179.6$ ft. M_2 , the deflection due to T_2 is 103.1 ft. $l_1 = 812.39$ ft., determined as before, and the length for the live catenaries is $4l_1 = 3,249.56$ ft.

The rope may be considered, without sensible error, as embracing one-half the circumference of the pulley at A , and one-half at B ; the remaining pulleys, being simply guides, do not affect the length sensibly. The total length of rope required is therefore

$$s = 2\pi R + 500.4 + 600 + 3,249.56 = 4,393.94 \text{ ft.}$$

(4). The Loss of Power.

Experience shows that only the friction of the shafts of the pulleys on the hearings diminishes the power in wire-rope transmission. Allowing a pressure of 4 P on each shaft, and a coefficient of friction of .1, the loss of power amounts to 9 H. P.; the available power is therefore at least 95%.

Wonders of Venus.

Many who admire the beautiful star which now adorns the western sky until more than three hours after the commencement of twilight, may not be aware that its splendor is derived from the sun; that in it, like on the earth, night curtains the landscape, morning dawns and seasons in quick succession come and go. Lofty mountains show that forces similar to those which upheaved the Alps and lifted the summits of the Andes above the regions of eternal snow, have ridged its surface and covered it with hills and vales. Variable spots prove that clouds float in its atmosphere, and gleams of light, which dart across its sky, afford evidence that in it lightning sears the sky and the thunder's roll reverberates through the valleys.

But 300 miles less in diameter than the earth, and revolving on its axis in nearly the same time, Venus makes thirteen revolutions around the sun while the former makes eight. As the inclination of the planet to the plane of its orbit is at least 54° , its torrid zone is double that extent, or 108° , and its polar circles 54° from the poles. It therefore has two frigid and a torrid, but no temperate zone. Since the sun must arrive at the equator and depart from it

to the distance of 54° twice in each of its years, there must be two summers and two winters annually in the torrid zones and a winter and a summer in each of the frigid. Venus becomes the morning star after its superior conjunction, when it appears, through the telescope, crescent-shaped like the new moon. The orbits of this planet and of Mercury are within the orbit of the earth, and consequently they are never seen in opposition to the sun, that is in the east when the sun is in the west, or in the west when the sun is in the east. At its inferior conjunction, Venus is nearer to the earth than any other planet except the moon, and sometimes when approaching the greatest distance, when it seems to recede from the sun, casts a shadow and is visible in the full light of day. If at the period when it is nearest to the earth, the enlightened part were fully turned toward the latter, this planet would appear twenty times as brilliant as it now does and almost vie with the moon in dissipating the darkness of night. Being situated at about one-third less distance from the sun than the earth, Venus receives more light from that luminary than is received by the former planet, and seems not to require the aid of the moon. Nevertheless, several astronomers have affirmed that they have noticed such a body, and have even gone so far as to calculate the orbit of the supposed satellite, but their observations have not been verified.

The transits of Venus, or its passage between the earth and the sun, when it appears as a round dark spot moving slowly across the solar disc, have been made to assist in determining the distance of the earth from the central luminary. The last transit occurred in December, 1874, and the next will take place in December, 1882. As this can be viewed in the United States it will awaken a greater interest than the transit which Rittenhouse and others observed more than a century ago. But four transits of Venus have been observed, and after 1882, 121 $\frac{1}{2}$ years will elapse before the alternately morning and evening star will pursue its seeming pathway across the surface of the great orb of day. — *Albany Journal*.

PHOSPHORESCENCE.—MM. Bancel and Huson have communicated to the Academy of Sciences observations on the phosphorescence of the flesh of the lobster. They consider it due to a fermentation in which carbo and phosphohydrogens are liberated, and which is destroyed by putrefaction, just as the bacteria of carbonaceous destroyed by the vibrations of putrefaction.

Australian Gold Fields.

The last Australian mail brings news of a discovery in one of the several mines at Ballarat, which bids fair to be of the greatest importance to the future prospects of the district, hitherto the most valuable alluvial gold field in the colony. The discovery was the finding of an extensive quartz reef in the claim of the Baud and Alhion Consols Company. The mine owned by that company has in the past yielded grand returns of gold from its alluvial washes, and the new quartz reef was found at a time when it was thought the rich alluvial ground was almost worked out. The first returns obtained from the reef, which was stated to be 20 feet thick, were at the rate of 12 dwt. per ton, but they speedily improved, until 350 ounces of gold were obtained from 250 tons of quartz. The following fortnight's crushing of stone was still better, 464 ounces of gold being obtained from 176 tons of stone, and the yield for the last fortnight was 396 ounces 12 dwt. The good effect of the discovery on the spirits of miners and those who are interested in mining property has been magical, and all the unoccupied land under which the new reef is supposed to run has been eagerly sought after for mining purposes. It is hoped, indeed, that Ballarat may yet prove to be as rich in auriferous quartz as it has hitherto proved in gold-bearing alluviums. The value of the discovery, so far as the claim itself is concerned, may be understood when it is stated that the shares of the company are now selling at five times the price they were disposed of only about six weeks ago. The mine is situated in Ballarat West, but the progress of quartz mining in Ballarat East is also very satisfactory. The Queen Company, a tribute to the Black Hill Company has struck a good body of stone, while the Suleiman Pacha has also come across a promising run of stone at the 300 level, on what is known as the Old Prince of Wales line of reefs, and near where the celebrated Welcome nugget was found. Other claims in the neighborhood are also stated to be doing well. At Beaufort, work is proceeding on many of the claims recently started there, and it is now probable that this long-neglected field will have a chance of being thoroughly developed by the influx of outside capital. An alluvial gold field was found about three weeks ago near Dunolly, which promises to be one of the best discoveries of the new ground that has been announced for a long time past. Nuggets of various sizes, from eleven ounces downwards, have been obtained in some of the claims at a rush, and a large number of miners have taken up ground wherever it is thought the gold will be found. At Stawell, one of our principal quartz mining districts, mining is said to be improving from the dullness which has pervaded it for the past few months. Only last week a kiln of 1,111 tons from the Oriental mine there produced the splendid yield of 3,480 ozs. 11 dwts., or an average of about 3 ozs. 3 dwts. per ton. The company had then 600 more tons of the same kind of stone ready towards another kiln. The miners of the Pleasant Creek Cross Reef Company, whose claim has, so far, been one of the richest worked in the colony, believe that the reef which gave the Oriental crushing just mentioned is close to their boundary, and if that be so, the mine is likely to be very rich indeed, there is nothing of special importance recorded in connection with the other gold fields of the colony, but work, however, is carried on steadily in all of them, and it is believed the yields are keeping up to the average.

DIFFUSION OF LIQUIDS.—In the course of a recent lecture at the Royal Institution, Sir W. Thomson made some experiments to show the extreme slowness of the diffusion of liquids. He exhibited tubes filled nine days previously, which in the upper part contained one fluid, and in the lower another, such as a solution of sulphate of copper, a solution of common salt, colored alcohol, etc. A mark where the two fluids met was registered at the time the tubes were filled, and in the nine days the diffusion had not extended upwards and downwards more than two or three inches. In a lecture-room at Glasgow a tube about 30 feet long was filled some years ago, and from the rate of diffusion it has been calculated that complete interdiffusion of the two liquids will occupy nearly 1,000 years.

CHARLESTON PHOSPHATES.—The rocks are of various sizes, from that of a hickory nut to a peck measure, and, although most of them are embedded in a tenacious clay or marl, at various distances from the surface, rarely exceeding ten feet, a considerable quantity lies loosely above ground, and until their true nature was discovered, a dozen years ago, were regarded as a great disadvantage to the land by the owners. They were detected by the farmers, like our northern drift rocks, which interfere with easy cultivation. These rocks extend over an immense area—hundreds of thousands of acres—and practically the supply may be said to be inexhaustible.

FRENCH CABLE.—The cable steamer *Faraday*, having laid the shore-end of the new French Atlantic cable from the coast of France, has returned to England to take on board the shore-end of the cable to be laid on this side, which she will at once proceed to lay down. The telegraphic journals express considerable doubts of the financial success of this undertaking, contending generally that there are already more transatlantic cables in operation than are required for the needs of business.

Aluminum and its Applications.

In an article contributed to the *Industrie blätter*, Mr. Clemens Winkler gives a history of the development of the art of working aluminum, as evidenced in the displays at the three international exhibitions at Paris. In 1855, aluminum was shown for the first time, at the Palais de l'Industrie, as a large bar, to which the extravagant name of "silver from clay" was given. In 1867, it appears again, but worked up, and betraying the manifold difficulties which had been overcome in its production on a large scale, its purification and its molding. It was exhibited in the form of castings, sheet wire, foil or finished goods, polished, engraved, soldered, and for the first time, and in varied forms, its most important alloy—aluminum bronze—was shown. After the lapse of almost another dozen years, the Paris exhibition offered, in 1878, evidence of the maturity of the aluminum trade. The time when aluminum was worked up in single specimens, showing the future capabilities of the metal, has passed, and now it has become an article of current manufacture, having a regular supply and demand, and being in some regards commercially complete.

The fears entertained as to the future of aluminum is thus seen to have been unjustified. The manufacture of aluminum and of aluminum goods has certainly not grown as rapidly as was hoped. The lowest limit of the cost of manufacture was soon reached, and aluminum is still a product extracted only by a series of expensive operations from one of the cheapest and most common of raw materials. On the other hand it is steadily displacing for a variety of purposes other cheap metals, over which it is seen to have incontestable advantages. Its color and luster are pleasing, while its peculiar lightness fits it in an unrivaled manner for many purposes, both of science and luxury. This low density has to be taken into account when the price of aluminum is compared with that of other metals, since it occupies, weight for weight, three times the space of iron, copper, brass and nickel, and four times that of silver.

To France is due the credit of having been the first country to carry out Wohler's process for the production of aluminum on a practical scale, and to have created the aluminum manufacture. France still seems to be the only country in which the manufacture is able to prosper. The English manufactory established at Washington, near Newcastle-on-Tyne, by Bell & Co., did not answer, and has been closed for about five years. The German manufactory set up at Berlin by Wirtz & Co., drooped before it was well started. In France, the great chemical manufactory of H. Merle & Co., in Salindres, near Alais, carries on the extraction of aluminum, and the Societe Anonyme de l'Aluminium in Nanterre (Seine), works up the metal into the various forms demanded by commerce. Both firms were represented at the exhibition. Merle & Co. had a splendid display of bars of this metal, while the Societe Anonyme exhibited samples of finished goods of all kinds, showing the progress made in its adaptation to various purposes. But for this it would not have been possible to exhibit reels of brilliant wire, fine as human hair, or beautiful sheets of extraordinary ductility. There were also exhibited stampings in aluminum—large medallions and pieces weighing exactly one gramme, to show the lightness, compared with the bulk of the metal. In one pan of a balance there were shown five large keys made of aluminum, which were counterpoised by a single iron key in the other pan. The peculiar bluish-white luster of the metal also compared to advantage with the use of tin and zinc. The beautiful objects made with great skill of aluminum bronzes, and sold at very cheap rates, are more popular than those made in pure aluminum, which is relatively dearer. Small articles of aluminum only are found to sell, among them may be especially named some pretty specimens of fine wirework. It is getting to be a common thing in Paris to make the frames for opera glasses and telescopes of aluminum. Houses which cultivate this branch of manufacture with success are Clermont, Lemair and Fischer. Still successful as is this application of aluminum, it is, perhaps, not the most favorable one. The most rational use indicated for aluminum, by reason of its low specific gravity, is the making of beams for balances. Aluminum bronze beams have been made for several years past; but, so far as lightness of metal is concerned, they have scarcely any advantage over brass. Sartorius, of Göttingen, was the first who made light and unalterable beams of an alloy of aluminum with 4% of silver. He has had but few imitators. The exhibition contained but one single balance the beam of which was made of pure aluminum.

This balance was exhibited by M. Collet; it carried 100 grammes, turning at 0.1 milligramme; its price was set at £80. There are several reasons for the small amount of favor shown to aluminum by mathematical instrument makers and others. First of all there is the price, then the methods of working it are not everywhere known; and further, no one knows how to cast it. Molten aluminum attacks the common earthen crucible, reduces silicon from it, and becomes gray and brittle. This inconvenience is overcome by the use of lime crucibles, or by lining the earthen crucible with carbon or strongly burnt cryolite. If any one would take up the casting of aluminum as a current industrial operation, there is no doubt the metal would be more freely used in the finer branches of practical mechanics.

USEFUL INFORMATION.

Coal Smoke.

Every one that has observed a soft coal fire, says the *Coal Trade Journal*, knows that the greater part of the black smoke that is sent off is because of the careless and ignorant way of feeding the fire. It is the same in steam boiler furnaces, in heating furnaces, in kitchen stoves, and parlor fireplaces. Also everyone that has tried it has found that to make workmen or workwomen feed the fire intelligently so as to burn this smoke, exceeds the power of the employer and housekeeper, even if the employer is not too careless to do it when he or she tends the fire.

In the case of steam boiler furnaces, as we have before times shown, the excuse for shoveling the fireplace full of coals is that the volume of cold air let in under the boilers, by opening the furnace doors to feed little and often, would defeat the economy. This is but partly true. The ease of feeding in the bulk way is the principal reason, and the average workman regards any increase of his care in order to save expense to his employer as an imposition on the workman. If women think it any easier with their help, let them try it with their Biddies and Gretchens, and see if they do not soon find that this is too great a disturbance to bear for what they can do in the smoke of reform.

They will find the same in feeding their open fires under their own noses in the parlor, and that even themselves, their husbands, boys, and relations will rather put on a lot of coals at once, and let them send off a black smoke for a quarter or half an hour before getting well ignited, than take the trouble of putting on a little at short intervals. But this easy conclusion on the part of all is what makes the bulk of our smoke.

In the case of steam boiler furnaces, this inability to get any care or intelligence or stoking has not even attempted to make such a feeding place by which the coals could be placed on the fire without letting in the cold blast. Yet any mechanic will say this is practicable.

Our information is that most of the burning of the smoke which has been accomplished in London is by the manner of feeding the fire. All know that if a small amount of coal is placed on a bright fire, the smoke is mostly burned. On the other hand, they know that if a large quantity is put on a considerable part is sent off in thick smoke before the fire recovers enough to burn it. All can see that if an apparatus were contrived at this mouth of the furnace, to place the coals regularly according to the rate of consumption on the bright fire, most of the smoke would be burned. And any mechanic will say that such an apparatus can be made to do this without letting in a cold air blast.

But it is requisite that this should be made to work with machine regularity, if not automatically, so that neglect and indifference and laziness shall not find it easier to stow in bulk. All will agree that it is entirely practicable to make such a feeding apparatus at no great expense. And there can be no doubt that the saving thereby would make it profitable. The expectation of some chemical mixture, or of some machine by which smoke shall be made so inflammable as to burn itself, will probably be disappointed, but at any rate the reduction of the smoke nuisance by a sub-division of the coal in feeding the fire is entirely practicable, and it appeals to every one's common sense.

THE MANUFACTURE OF ICE IN THE SOUTH.—Few people have a correct notion of the extent to which artificial ice is being manufactured in the South. The success of the process employed has been so marked that from Florida to Texas the machines are being put in operation at frequent intervals. The actual cost of manufacturing ice on the St. John's river is said to be but 70 cents a ton, including the storage and delivery. As Northern ice used to retail at from \$10 to \$15 a ton there, it is plain that a handsome profit remains for the manufacturer after putting his price as low as to drive all natural competition from the market. One of the "Arctic" machines, in which ammonia is used to do the freezing, turns out ten tons of ice daily, in the form of blocks, about two and a half feet long, and ten inches in thickness. The congelation is perfect, and many are said to prefer ice thus made to that formed in the laboratory of nature.—*Savannah News*.

PHOTOGRAPHING SEALS.—A photographer in Germany has made seals and stamps with the portraits of his customers. A thin layer of gelatine sensitized with bichromate of potash is exposed to the action of light under a photographic positive, by which the parts acted upon are rendered insoluble in water. The gelatine film is immersed in water, and the parts not acted upon by light swell up, and we obtain a picture in relief, of which a plaster cast can be taken. A galvanoplastic copy being taken of the cast, we have a metallic fac-simile of the photograph, which can be employed as a seal.

ACTOS AND "GRANITE" WARE.—A correspondent of the *Druggists' Circular* writes as follows: "I have discovered that oxalic acid is very destructive to the enamel of the iron ware. Perhaps the knowledge may be of use to druggists and others using it. Another objection is that it scales off, leaving the iron exposed, which colors some preparations."

JAPANNED WARES IN ENGLAND.—The chief seat of the manufacture of the lacquered, or so-called japanned, ware in England is at Wolverhampton, where at least 100,000 trays and waiters are turned out in a week, when trade is good. Most of these, however common, used to be painted by hand, with astonishing celerity of execution. It was said that a "skilled artist" could with ease paint two gross of landscapes in a day. Most of this common decoration is now effected by the new method of transfer printing, for which, probably, porcelain decoration suggested the idea. The pattern or picture is printed by the lithographic process on fine tissue paper, which is laid face downward on the japanned plate, and adheres to the sticky varnish with which it has been treated. After a time, the paper can be wiped off, but the colors remain, and are afterwards fixed by stoving. A new decorated tin has come into the market printed in the sheet, it is said directly on the metal, with such permanency as enables it to be made up afterwards into canisters and other articles without injury, and this has very much cheapened the production of those articles.

PREPARING CRYSTALS.—For preparing regular crystals of any size, the *Archiv des Pharmacie* gives the following directions: "You make a solution of the substance, of such concentration that, after 24 hours, a part of the salt becomes separated in crystals. Take some of the finest of these crystals and place them on a glass in a vessel which is higher than it is wide. Dissolve a little of the dry saline mass in a quantity of the mother-water; add this solution to the whole of the mother-water; then sprinkle with this liquor the crystals placed on the glass plate. After about 12 hours separate the liquid, and dissolve in a small portion of it, again, a little of the dry salt; mix the solution with the mother-water, and pour the whole on the crystals on the glass. You repeat this operation every 12 hours, until the crystals have acquired the size wished. The vessel containing the crystals, preferably, be placed in the cellar."

IGNITING TINDER, ETC., BY COMPRESSED AIR. The common experiment of igniting tinder by compression in a glass tube does not always succeed; the tinder may not be ignited, or may not retain its glow, after the piston is withdrawn. Tyndall uses sulphide of carbon vapor instead of tinder. Hofmann says both may be advantageously replaced with gun-cotton. A little ball of this, the size of a pea, always ignites, with lively flame, visible to a distance. The experiment might be dangerous if large quantities of the substance were used; but, in the way indicated, it is not. Gunpowder may also be used for the experiment; but it does not ignite with the same certainty.

TO PRODUCE COLD BY VAPORIZATION OF ETHER.—Prof. Hofmann, in a communication to the Berlin Chemical society, recommends for this purpose placing a test tube half-filled with water in a cylinder containing ether, so that the ether reaches somewhat above the surface level of the water. A current of air being sent through the ether, the water is soon changed into a transparent cylinder of ice.

KEROSENE FOR SOFTENING LEATHER.—It is said that kerosene will soften boots or shoes which have been hardened by water, and render them as pliable as when new; but we fear that it will injure the leather. Castor-oil, long ago commended in the *Journal*, is doubtless better.—*Boston Journal of Chemistry*.

GOOD HEALTH.

THE AMMONIACAL SULPHATE OF COPPER IN TIC DOULOUREUX.—Dr. Fereol, of the Lariboisiere, has met with an amount of success in the use of this almost forgotten remedy in four cases of old and obstinate tic douloureux, that leads him to believe that it is one to which attention should again be drawn. He prefers the fluid form, as in the following mixture: Distilled water, 100 grammes; syrup of orange or mint, 30 grammes; and ammoniacal sulphate, from 10 to 15 centigrammes. This is to be taken chiefly at meal-times, within the 24 hours. If the neuralgia persist, the dose may be gradually increased; and in one case as much as 60 grammes per diem was given, but then began to cause gastro-intestinal disturbance. Even in the ordinary dose, after two or three days, fetid breath and a metallic taste may be perceived; but, in spite of this, the medicine must be continued at 10 centigrammes per diem for 12 or 15 days, especially at meal-times.

TRANSFORMATIONS OF NERVOUS PHENOMENA. In reviewing the affections and the nervous phenomena which are propagated by a transmission and a transformation of motion, from simple yawning to epilepsy, fascination, panic, etc., J. Ramhossion formulates the following general principle: A purely physical movement may be transformed into a physiological and into a psychic or cerebral movement by simple transmission to special portions of the system, and reciprocally, a psychic movement can be transformed into a physiological and into a physical movement by simple transmission to a different portion of the system, and that without losing its character; for it reproduces the same phenomena, after all these transmissions and transformations.—*Comptes Rendus*.

BANDAGING IN MIGRAINE.—Dr. Weir Mitchell (in the *Boston Medical and Surgical Journal*), relating a case of migraine occurring in a girl seven years and a half old, exhibiting the congestive type, and for which he prescribed small doses of bromide (*gr. iij.*) and tinct. belladonna (*gtt. iij.*), observes that the use of the old domestic remedy, a tight bandage, during the attack, is useful. He employs a rubber bandage, applied thoroughly from eyes up with a thin pad over each temporal artery, if the temporal ridge be sharp enough to keep the bandage from squeezing the arteries, and over the two occipital vessels. Instead of caoutchouc, a well applied muslin bandage may be put on, and then wetted, using compresses over the temporal arteries. The comfort thus given is sometimes surprising. He adds: "I need not say that migraine in some of its forms become at times— and especially in women—a most disabling malady, and may recur daily, until life is a burden impatiently borne. These are usually cases of thin-blooded and thin people, whose sufferings are brought back by the attempt to take exercise, without an abundance of which a return to health is out of the question. I have seen some such cases in which a cure little less than marvelous has been made by the use of absolute rest, over-feeding and massage. There is, of course, much more to be said on the therapeutics of migraines, but no one drug is its master. The hint as to thorough bandaging is worth remembering, and especially at the close of a headache."

SUN CURE.—Says the *Cincinnati Artisan*: A warm and dry atmosphere is not unwholesome, but when cloudy or rainy weather brings a sultry air which dampens everything around us, the atmosphere may be loaded with germs of disease, and fire is needed to destroy them. The walls, the ceilings and the floors of apartments should never be allowed to become damp. Sometimes, when the warmth of the air is oppressive, fire is more necessary to preserve health than it is at another season to protect us from the cold of winter; and the rooms of a dwelling should never be left without the means of warming and drying. Investigations have shown that many of the most fatal diseases are caused by the germs of vegetable and animal life, and that a humid atmosphere is most favorable for their propagation. It is, therefore, neglecting to avail ourselves of the great discoveries of the age, and failing to protect ourselves from the scourges which so fearfully afflict families, when we ignore the dangers which surround us. Apartments exposed to the full action of the sun may be less comfortable in hot weather than those from which the sun's rays are excluded, but they are more wholesome, and when contagious diseases prevail in closely-built cities, it is found that the inmates of houses on that side of the street exposed to the sun are less liable to be attacked, while the greatest number of sick are always found where there is the least exposure to the rays of that great disinfectant—the sun.

THE TONGUE AND THE SENSE OF TASTE.—The tasting power of the tongue is not regularly distributed over all parts of that organ. According to the unanimous judgment of physiologists, the back part of the tongue is best qualified for this function, while there is a difference of opinion as to the tip of the tongue. The older observers have repeatedly said that a tasting power in the tip is limited to certain persons, whereas more recent ones affirm its presence in all men. In experimenting on the so-called "reaction-time," Herr Vintschgan lately met with a case of limited tasting power in the tongue-tip, and this led him to a thorough investigation of the subject. The observations were made with solutions of chloride of sodium, sugar, quinine and citric acid. The results were as follows: There are persons who are capable of accurately distinguishing all principal tastes with the tip of the tongue alone; others perceive with certainty the qualities of sweetness, saltiness, acidity, but less distinctly bitterness. Others, again, can only with great difficulty distinguish tastes with the tip of the tongue; and, finally, there are individuals who cannot do this in the least.

BORAX AND NITER FOR HOARSENESS.—*La France Medical* remarks that these two salts have been employed with advantage in cases of hoarseness and aphonia occurring suddenly from the action of cold. The remedy is recommended to singers and orators whose voices suddenly become lost, but which by these means can be recovered almost instantly. A little piece of borax, the size of a pea, is to be slowly dissolved in the month ten minutes before singing or speaking. The remedy provokes an abundant secretion of saliva, which moistens the mouth and throat. This local action of the borax should be aided by an equal dose of niter, taken in warm solution before going to bed.

HYGIENE VS. LONG TRAINS.—The municipal authorities of Prague have, at the request of this Board of Health, interdicted the wearing of dresses with trains in the public streets, on the ground that the dust raised by those appendages is injurious to health. In Algeria the clouds of dust raised by the incessant sweeping of the long skirts of the ladies produce on the legs, when bathed with perspiration, an irritating pruritis and eruptions, which are only partially relieved by baths and a scrupulous attention to cleanliness.—*Exchange*.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The New Era in California Gold Mining; An Improved Pipe Threading and Cutter; Petroleum as Fuel; A New Ore Crusher; The Liverpool Copper Market, 113. The Week; Prehistoric Researches; Mining Business in Quarantine; Lunar Influence; The Defrauded Element, 120. Fresno County Mines, 121. An Infamous Business; Notices of Recent Patents, 124.

ILLUSTRATIONS.—Saunders' Improved Pipe Threading Hand Machine, 113. North Fork and Minaret Mining District, Fresno County, 121.

CORRESPONDENCE.—Foundries in Nevada Mines, 114.

MECHANICAL PROGRESS.—The Westinghouse Brake; A New Stone Dressing Machine; Compound Locomotive Engines; New Electro-Magnetic Motor; The New Telephone, 115.

SCIENTIFIC PROGRESS.—The Manufacture of Soda, Potash, Etc.; Gas-bit Boilers; Utilizing Iron and Steel Scrapings; Smoke of an Electric Lamp; Prehistoric Stone Implements, 115.

MINING STOCK MARKET.—Sales of the San Francisco, California and Pacific Stock Boards; Notice of Assessments, Meetings and Dividends, 116.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Idaho, Montana, Oregon and Utah, 117-124.

MISCELLANEOUS.—The Manufacture of Venetian Glass; Making Phosphide of Hydrogen; Montana; Importance of Testing Water Pipes and Pipe Joints; Cleaning and Tinning Metal Plates, 114. A Problem in Transmission of Power; Wonders of Venus; Australian Gold Fields; Diffusion of Liquids; Charleston Phosphates, 113. Aluminum and its Application, 119. USEFUL INFORMATION.—Coal Smokes; The Manufacture of Iron in the South; Photographing Seals; Acids and "Granite" Ware; Japanned Wares in England; Preparing Crystals; Igniting Tinder, etc., by Compressed Air; To Produce Cold by Vaporization of Ether; Kerosene for Softening Leather, 119.

GOOD HEALTH.—The Ammoniacal Sulphate of Copper in the Douloureux; Transformations of Nervous Phenomena; Bandaging in Migraine; Sun Cure; The Tongue and the Sense of Taste; Borax and Niter for Hoarseness; Hygiene vs. Long Trains, 119.

NEWS IN BRIEF on page 124 and other pages.

Business Announcements.

Mineral Lubricating Oils, F. B. Taylor & Co., S. F.

The Week.

The week has not been remarkable for any very great diversity in stocks. An apathy has seemed to prevail out of which the market could not be roused. A strong disposition has been manifested to compel investors to purchase upon mere individual representation, a policy which will not prevail for the reason that sad experience has demonstrated too often that dishonest transactions are covered up by an air of mystery. The public are becoming weary of the continual talk about "expectations" in the flooded mines of the Comstock, and seem to realize that perhaps the anxiety to free the mines of water is not so great as it should be. Probably the instinctive doubt whether the removal of the water will disclose anything more of value, has something to do with the mysteries now enshrouding the operations. The Comstock market has evidently lost tone considerably, and, for all we now know, may never be brought above the level at which it stands. It is quite true that the Washoe bullion product has been equal to double the amount of assessments, but this spread over many years will not amount to more than an ordinary percentage on the money invested. It is, perhaps, just as well to come down to hard facts and say that the total dividends from the Washoe district has been \$114,589,700; assessments, \$54,865,635; leaving \$59,724,065 profit. A little more than 100% which, distributed over 20 years, which is about the length of time the Comstock has been in operation, would make an interest of about five, at most six per cent. Not so very much after all. The immense fortunes realized have not been acquired on this income, that is patent. Now, how did some of our noted manipulators get their millions? By stock-gambling, or by straightforward business transactions? Every man must judge for himself. All these hard facts are becoming known, and hence no surprise need be felt on any loss of "tone."

Prehistoric Researches.

The vast physical changes that have occurred on the surface of the earth within the memory of living men, and the elevations and depressions taking place at the present moment, has more to do with the solution of the theoretical problems concerning man's antiquity that have been presented to our notice at various times, than would be naturally supposed by the casual reader.

The evidences of the prehistoric existence of man in Europe and America consist of relics of various rude manufactures, such as rough pottery; stone implements, broken bones, and shell beads; of rough drawings of extinct animals, and of human fossils, either in ancient geological strata or in connection with the remains of certain extinct animals. The human period is divided into three ages, designated by the kind of material used in the manufacture of weapons and implements, as the Stone, the Bronze, and the Iron ages. The Stone age is also divided into the Paleolithic, the Reindeer, and the Neolithic eras. The first of these indicates a time when the manufactured implements were rudely made of unpolished stone; in the last they were of polished stone, with other evidences of a more advanced state of civilization. The Reindeer era seems to have been a period when a second glacial condition drove the animals and people of Northern Europe southward, where many of them left their remains embedded in the sedimentary deposits of that time. Some of the oldest relics of man are found in certain peat-beds of Denmark. These vary in depth from ten to thirty feet. In these, at various depths, are found embedded the fallen trunks of different kinds of trees.

Other memorials of man's early existence are found in the shell beads or mounds of Northern Europe, and found likewise in many places in the United States. The connection of the human remains and the shellfish of the period are regarded as evidence of contemporaneousness. Certain bones have been found bearing marks and scratches that have been thought to be the product of human hands. Rudely-chipped bits of flint supposed to be hatchets, knives, spearheads, etc., are found in great quantities in many places. These are associated with the fossils of an extinct elephant, rhinoceros, lion, and cave hyena, besides those of some animals yet living. It has been supposed that the juxtaposition of the bones proves that man was contemporaneous with the other animals named. But there are many doubts about the nature, relations, and time of life of these flint chips. Some maintain that they are not of human workmanship at all, but only the result of the action of frost on the quartz rocks. Others admit their human origin, but claim there is no satisfactory evidence that human beings lived at the time the animals did.

These remains are generally found buried deep in the earth, either commingled or lying in distinct horizontal strata, or in surface locations. In both cases in or near the old bed of a river, with every indication that in the first case the remains were deposited under the violent action of water, occurring at different periods, and in the latter case the overlying strata of detritus have been washed away, leaving the remains exposed to view. Animal remains, as of buffaloes, have been found in Colorado and other places contiguous, where whole herds have been engulfed by the action of some cloudburst or land slide, and it needs only a few human remains and implements deposited there by some previous or subsequent similar convulsion of nature, to justify the contemporaneous theory.

It will not do to relegate all of these evidences of man's antiquity to some date in the vast geological past, for we may logically assume that the changes which operated to hurry and commingle from time to time, these various strata in one common grave occurred then as they do now, and in the same manner and in less time than now, because the configuration of the geological features were more prominent and more liable to the action of the elements. Many gradual elevations and depressions of special localities are going on during our own age. Southern Italy has been subject to vertical oscillations of 20 feet or more within historic times. The Andes have been depressed 220 feet in the last three-fourths of a century. The northern part of Sweden is undergoing gradual elevation. Many changes of this nature are now going on at various localities along the eastern coast of North America. More sudden changes, that produce greater changes in a few hours than the above noticed will in as many centuries, have occurred in quite recent times. We have seen the whole coast of South America lifted up 10 or 15 feet and let down again in an hour. During an earthquake in 1819, 2,000 square miles in Southern Asia sank and became an inland sea, while adjacent to it a belt of country 20 miles long and in places 10 broad was lifted up 10 feet above its former level. With regard to the coast on the Baltic, we have evidence of a very important depression since the existence of man. While digging a canal near Stockholm the workmen came upon a fishing hut at a depth of 60 feet. And as this subsidence is still going on, it seems to stand in corroboration of the theory that at no very distant day, as compared with the lapse of time claimed by some, that region stood many feet higher than at present.

Mining Business in Quarantine.

It must be apparent even to a superficial observer, that the business of mining, although widely different from most kinds of business, may be as wisely and as honestly conducted as any other. There is no necessity for drawing the distinction between the legitimate and the illegitimate in this business, because only what is legitimate can be dignified by the name of business, all else is a dishonest swindling transaction. The speculative tendencies which surround the affairs connected with mining operations have their origin in the cupidity of man as have all other speculations, a mere wager that a certain amount of bullion will be yielded by a given mine, the quantity being gauged by the imagination of the owner. This element of chance, so fruitful of abuse, is what brings odium upon our mining operations. There are individuals who will speculate in stocks as there are those who will gamble at cards, and speculation is at best but a species of gambling. That there is rich ore in the soil of our Rocky Mountain States and Territories needs no demonstration, and the fact that the supply of bullion from our mines exceeds the amount realized from any other business, should be a patent fact to all that our estimates of mine value have not been drawn wholly from imagination. From the fact that within 20 years the world's supply of gold fell from 200,000,000 a year to an estimate of 70,000,000 during the present year, we do not infer any great disaster. Twenty years ago the demand for gold was greater than it is at the present time, besides other than mining interests have been developed to an enormous extent. We might say that when the same requirements exist in future, as existed in the past, the supply of gold will be increased. It is not strange to us that Russia should now come to the front as a gold producer. That nation has arrived at that point in its existence, when the universal medium of exchange, gold, is essential to her existence, and, hence, her strenuous efforts to produce bullion.

The yield of bullion per capita of the Pacific coast is greater than that of any other country in the world, being about 40 times that of Russia, or taking the whole population of the United States as a basis, it would be twice that of Russia. There is a large margin here, in favor of our bullion yield, which the demands of commerce will increase when necessary.

It is certainly true that our precious minerals have built an empire on this coast, but precious minerals alone will not maintain it. There are other elements of fully as much importance to society as gold production, which other elements are essential to our mining business, as is our mining business to them. The agricultural interests of the coast are large, and our productions from that source have realized a remunerative income. Yet it would be unwise to say that agriculture alone can sustain our prestige. It is, in part, due to our gold production that we have been able to maintain our agricultural resources, and, perhaps, we may say that at the present time our agricultural resources are an aid to our bullion produce. It is certain at any rate, that gold took the initiative, and laid an enduring foundation of prosperity, and it is useless for agriculture to come in now and claim the honor. The immense tracts of land in the mineral regions are suitable for mining, and comparatively useless for any other purpose, and to mining it should forever be appropriated. That is the plain intent of our laws. Whenever agriculture and mining clash, it is a house divided against itself, and disaster may then be said to follow. It is much easier to glut the market with wheat than it is with gold, and this point should not be overlooked in any desire to make one prevail to the exclusion or detriment of the other.

Lunar Influence.

Prof. J. P. Nichol, the eminent astronomer of Glasgow, in a letter to the Boston Journal of Chemistry in regard to the supposed influence of the moon on the weather, says:

"No relation exists between these classes of phenomena. The question has been tested and decided over and over again by the discussion of long and reliable meteorological tables nor do I know any other positive way of testing any such point. I confess I cannot account for the origin of the prevalent belief."

The origin of the belief in the moon as an influential power over our earth must be traced to the ancient superstitions concerning the influence of the moon on mundane affairs. Many lingering superstitions have their roots in the old mythology and astrology. These died as systems long ago, but popular notions that grew out of them, still live among the illiterate in all lands, and sometimes their ghosts haunt even the educated. The changes of the moon cannot affect us in the least, because these changes occur all the time at every point of the moon's orbit. There is no powerful metamorphosis in the moon at the "first quarter," "full moon," or "new moon," any more than there is between those points. The changes in the appearance of the moon is due solely to the rays of light striking the body of the moon at certain angles or points. The moon is always the same, changes are only in the reflection of the light, and the moon itself can no more be said to change in the ordinary sense of the word

than a railroad train changes when it passes a mile-post set up beside the track. The light of the moon cannot affect us because it is of such small degree—619,000 times less than the light of the sun—a lantern hung on a pole would affect us just as much. There is no heat to speak of in the reflected light of the moon, and, as is ignorantly supposed, does not produce cold. The stories of persons having distorted limbs and countenances by reason of sleeping under the rays of the moon are "mariners' tales." To assume that the influence of the moon can be perceived and understood by uneducated observers, and made a part of popular "weather wisdom" and applied to practical use by farmers, or sailors, or anybody else, while scientific observers, who have spent years of experiment and with the most delicate instruments, know nothing about it, is simply ridiculous. There is no *raison d'être* in the phenomena attributed to the moon.

The Defrauded Element.

We have always deprecated the manifest injury to the community caused by swindling mining stock manipulations, and we contend that there is no reason why the mining business could not be carried on with advantage to the investor. Of course there are "wildcat" schemes which have no community of privilege with an honest business. There are certain badges of fraud about them which are plainly visible to the most superficial observer. But even legitimate enterprises may be manipulated for purposes of deception, so that the public are misled by an infamous cheat under the cloak of an honorable name. Laws have been enacted to protect the public from imposition, but laws do not meet the requirements. All the liquor laws in the world, combined with all of the efforts of lecturers, and the blood and tears of sorrowing women and children, have not barred one whit the progress of the evil of drunkenness, or stayed the manufacture and consumption of spirituous liquors. Nor has all the outcry against cards, faro and other games of chance abated the folly which rushes to the pecuniary destruction and even suicidal mania engendered by their abuse. Why? Because human nature and all of its susceptibilities remain unchanged. When men have been directed aright, and when the evils of a certain line of conduct is pointed out to them by a long list of experiences, it would seem as if some faint glimmering of common sense should save them from disaster. The responsibility of every individual man, arising from his influence over others, under these circumstances may be said to be released, were it not for the fact that the memory is not altogether perfect, nor the application of fixed rules governed by a sense of nice discrimination. Some go to the left intending to go to the right, governed by the same disposition which guides a man in a forest in a circle. Not entirely an unreasoning, unthinking sense of duty, but a hope that the outcome will be favorable. It is this latter spirit which has caused so much delusion, and the knowledge of which that has nourished a crop of vultures which prey upon man's natural cupidity and hopes by glittering humbugs. Let prohibitory laws come to the rescue if they can, but as long as human laws can only appeal to the senses and not affect the intelligence, just so long will there be defrauders and defrauded. The body politic has to do with the entirety of the community; and the *raison d'être* of its laws, rules and regulations whether local or general cannot have any other object or application. Every man must reason out his affairs to his own advantage. We sorrow with the unfortunate loser in some mining swindle, but what shall we do to relieve him? Shall we imprison or kill the knave who robbed him? If we do, another and a worse one would spring up on the morrow. Might it not on the whole be as well to confine the party who has allowed himself to be deceived, upon the principle which obtains among some Oriental tribes, that the individual who permits himself to be so ingloriously swindled has not sufficient common sense to justify his remaining at large. *Caveat emptor* is a maxim of law founded on common sense and is a general answer to these grievances. He who needs a law to protect himself against his own acts needs also a guardian. We are not arguing in favor of the ecclesiastics who put up jobs on unsuspecting individuals, we only desire to impress the idea that if there were no gullible parties, the gulls would find their occupation gone.

TEA ADULTERATION.—Dr. J. M. Eder is the authority for the statement that one-half of all the tea sold is mixed with spent tea leaves. Processes for the sophistication of tea are considered valuable property, and if there has not been some misinformation sent abroad, the owner of a tea-doctoring secret lately sought protection in its use from our courts. Among dealers of an article so generally used as tea there is a keen competition, and the temptation to have recourse to swindling as a fine art is strong and sometimes irresistible. By and by the evils will compel a remedy.

KEEPERS of gambling places, dance houses and Chinese opium dens at Modesto were ordered by the citizens to close up Thursday night and leave town within 24 hours.

Fresno County Mines.

[Written for the Press by J. W. A. WRIGHT.]

The mineral belts of the North Fork and Minaret districts in eastern Fresno, along the headwaters of San Joaquin river, well deserve the careful attention of the mining world by the number, extent, and good assays of their silver-bearing quartz ledges. Following the river's course, they are over 300 miles from San Francisco bay. A matter of interest in their consideration is the possibility that they are extensions of the already famous belt of Lake district, in Mono county, but a few miles distant across the Summit ridge of the Sierras. From the southeastern ends of the ledges of Minaret district, as far as they have been prospected, to the north face of Mineral hill, where the tunnels of Mammoth mine are located, is only about two miles in a direct line across the eastern spurs of Mammoth or Punico mountain. The general bearing of North Fork and Minaret districts is from NW. to SE.; that of Mammoth ledge is S., 54° E. Hence the three belts form very nearly a continuous line from NW. to SE., not far from 15 miles long and about a mile wide, enclosed in granite walls to the east and west. Judging from the latest developments in these three interesting districts, and the adjoining Prescott and Laurel districts of Mono county, it is no doubt safe to say theirs is destined to become one of the most productive mining regions of either California or Nevada. This sketch will be devoted especially to Minaret and North Fork districts, the former named from the splendid sharp, numerous chimney-like peaks, called the Minarets, and located to the westward of it, across the deep gorge that here forms the narrow valley of the Upper San Joaquin; the other district being improperly named by its discoverer from the erroneous supposition that it was on the North Fork, some 10 miles farther west, when in reality it is on the east side of the main river.

As far as your correspondent could gather facts, with careful seeking, the first time a white man gave special attention to any of these ledges, was in the days of the "cement bunters," of which Mark Twain's inimitable pen gives some account. In the summer of 1865, an

Indian Chief, Shohoc.

A guide to one of the many parties that joined in the mad hunt for the noted "red cement," said to be more than half gold, led Mr. James F. Wilson to what is now the principal ledge of the Minaret district, believing that the sulphuret of iron, or "fool's gold," in it was the genuine article. Mr. Wilson thought little more of it till the new excitement from the discoveries in Lake district two years ago. He legally located this ledge, naming it Shohoc, in memory of his Indian friend, June 6th, 1878, by an odd coincidence the same date, as given your correspondent, when the Advance ledge was located in the so-called North Fork district, at a point three or four miles farther northwest. In the summer of '78, a number of other valuable ledges and extensions were located. But, strictly speaking, the first real location in this region was made in the summer of '77, northwest of the Advance ledge, by Harry Kirkwood, from the Borden country, who was then herding sheep in the present North Fork district. The following June he told his discovery to J. S. Lingo, a prospector of long experience, just returned from Little Cottonwood district, in Utah Territory. They set out for the district for further prospecting and locations, and arrived about the 25th of July, to find that T. G. Agnew, present recorder of the district, and W. H. Morris had previously arrived from the Bodie side, the former having located Advance ledge, June 6th; the latter, Sentinel mine, its southeast extension, July 10th, and Nevada, on a parallel ledge east, July 12th. Messrs. Lingo, Kirkwood, M. Baker and Julius Hansen then located the Eureka, and J. B. Beasore soon became a partner. Up to the time of my visit, July 11th to 14th, the following ledges and extensions had been located in

The Minaret District,

All or most of them believed to be true fissure veins. By Mr. Wilson, in regular succession from west near the river to eastward up and over Summit ridge, at altitudes from 9,800 to 10,500 feet: Bona Fide, Joaquin Jim, Silver Cloud, Van Horn, Shohoc, Occidental, Twin Mounds, Blue Ledge, Lima and Sheba. At least six other allied ledges have been located; among them, Chieftain, Ruby and Silver, by H. N. Potts and S. P. Hall; Baltimore and Belfast, by F. Sotcher; Savage, by Hall and Cernike. Several claims were then being prospected by Mr. Elsey near Wilson's camp, but I did not learn their names. I have since been informed that one from one of these new ledges has assayed over \$300 per ton. On the high rocky ridges, on west side of main Joaquin, opposite Wilson's camp, the Exchange and other ledges have been prospected and located, appearing to be well charged with sulphurets of silver.

In case any of your readers hear of Wilson City, in "these diggings," please remember it is a name facetiously applied by the miners for purpose of locations to Wilson's camp, 9,800 feet up, near Bona Fide claim. This may prevent the disappointment expressed by two men who, after a long mountain tramp, packing their blankets, had been guided here by a packer board, in the meadow below, labeled Wilson City. On

arrival at camp they saw only a tent, a brush screen and a camp fire in a little notch on a steep mountain side. They asked, "how far to Wilson City?" When told, "this is it," they could only exclaim, with a blank look of astonishment and disgust, "Jerusalem!" They were too full for further utterance, but not full enough to be happy.

The Nature of the Minaret Ores

Varies somewhat in the different ledges. No sulphurets of zinc or lead have yet been found. As I learn from Mr. Wilson, the Bona Fide ore contains black and gray sulphurets of silver and a fine light yellow sulphuret of iron yielding considerable gold. Joaquin Jim, named for the Piute chief who led the Indians in the Owens River war, is separated only by a 10-inch ledge of talcous slate, from the preceding ledge, and produces a similar ore. The next two are similar ore, very fine grained. The Shohoc ledge, which Mr. Wilson deems the principal one, and hence calls all his ledges the "Shohoc Con.," carries sulphurets of iron yielding silver and gold, the former largely predominating. Next two, somewhat like this; but the Blue ledge produces a dark gray ore, more porous and spongy than in other ledges. These veins vary in apparent width from 10 to over 100 feet. None have been prospected to a greater depth

extensions, the C. A. Fox and Ohio. Next, east and corresponding with these, are the Riverside, De Soto and San Joaquin. That these locations may be better understood, we should state that south of this mineral belt in a low land, separated from the San Joaquin by a ridge, is quite a body of valley land, moist and rank with luxuriant pasture plants, and known as Agnow's meadows. On the northeast edge of this well-fenced pasture, a site has been selected for the future town of this district, to be known as

Highland City.

Here, in a handsome grove of firs, which abound in this whole well-timbered region, the pioneer merchant of all that country, outside of Mammoth City, 10 miles southeast, is Mr. Smith Norris, formerly of Borden. His storehouse consists of logs built up in cabin form three or four feet and covered by a canvass tent, though he will build a good log store for the winter. His pack trains keep up supplies by regular trips to Borden, about 100 miles southwest. All success to Highland City, its merchant and his customers! The altitude of the town site is about 9,500 feet. This altitude of the upper point of Advance claim is 10,700. It is about two miles northwest of Highland City, and the Blue Grass, its most southern extension,

feet. With this they hope to reach the ledge early in August.

The Site of a 1,000-Foot Tunnel

Has been located by F. F. Letcher, formerly of Santa Cruz, at a point about a mile southwest of Highland City. It is intended to strike the extension of several ledges already named. One he expects to reach in 80 feet, and at least one more, possibly five more in this 1,000 feet. He has also filed on the new town site, and proposes a tunnel farther west, to pierce Amazon hill.

The Few Assays

Are very satisfactory for mere surface ores. The Eureka and Surprise ores are found to be good types of all the more easterly ledges in the slate belt. They show sulphurets of silver with some galena. The latter shows less and less as they go deeper. Only about half as much of it appears 15 feet down, as on the surface. In the Eureka, no zinc, arsenic, or antimony has yet been found, but some antimony appears in other veins. The Eureka ledge dips between 60° and 70° N. E.

A dark ore of the Surprise has assayed \$52 silver. Two other assays yielded \$108 and \$109, while a third in San Francisco gave \$243 silver. Ores from the Homestake, owned by C. A. Fox, who, with Mr. Norris very kindly rode with me through this district, and found me opportunities for the information sought, has assayed \$71 and \$74. Cap ore from the Amazon, which is an immense ledge, averages \$8 to \$12. A striking mark of all the ledges in these new districts is their great width. The amount of ore in most of them is so great as to be almost incredible. Besides, mining districts could not possibly have better facilities for water, timber, tunneling, and drainage.

The Advance yields free milling ore, and is considered a fair type of the west lines of ledges, all but the DeSoto, a very peculiar looking ore, showing some antimony. Most of these ores contain iron sulphurets, but almost in this form of dust.

Having mentioned the abundance of timber in these districts—mostly firs and yellow pines—I must tell you of the uncommonly large California junipers—so like the red cedar of the East—growing near DeSoto ledge on a precipitous cliff, some 500 feet above the river bed. They are numerous, the largest measuring 22 feet in circumference near the ground. Its chief trunk is hardly 40 feet high. Its general appearance is wonderfully like representations of the celebrated "Cedars of Lebanon."

The Fall of Snow

There last winter, great as is the altitude, was not heavy, the ground being covered at no time to a greater depth than five feet. Snow fell in September and October, but soon melted. The ground was covered from the latter part of January till the middle of May. Usually, in our wet winters there would, of course, be much more snow than last winter. Yet the temperature was so mild—though the last was one of our coldest winters—that it never interfered with work there, and men could go about comfortably without a coat during most of the day-time. These facts I learn from Mr. Dodds, who spent the whole winter there, and Mr. Fox who was with him most of the time.

The sketch would be incomplete if I failed to mention that in Peck's meadow, in the valley below Wilson's camp, a site has been chosen for the future Minaret City; altitude about 8,900 feet. Near it is a remarkably fine soda spring, the water of which seems also to be impregnated somewhat with iron. It, and a warm sulphur spring, temperature 100°, in Pott's meadow, about two miles farther down the river, will no doubt be useful medicinally in the future.

In closing this letter, I can merely allude in brief to the many grand views in and around these mining districts, and to their fine lakes and streams which they are very anxious to have the State Fish Commissioners stock with fish. Mr. Sotcher proposes to try some Mountain trout in a fine lake near the meadow, owned by him and Mr. Potts. Its temperature was 59° in July. The trout are caught in large quantities by Indians at a point below San Joaquin falls, about nine miles down the river from the meadow.

Shadow Lake and Surroundings.

Few more beautiful and grand mountain views can be found in California, than the great amphitheater and other charming features around Shadow lake. But space forbids any attempt at description farther than, that you see it best from the neighborhood of Coprolite, or Thumb peak, on a northern slope of the Summit ridge, or from the top of Advance ledge; also, that it is formed by what the miners call, the Minarets and Cathedral peaks, towering in a huge semi-circle 13,000 feet high in places, Shadow lake lying placidly between 3,000 and 4,000 feet beneath them, and 1,000 feet or more below your point of observation. The lake is surrounded by forests of fir, and vast masses of perpetual snow. The entire view there, or from the top of Summit ridge, is impressive and enchanting in the extreme. Mts. Lyell and Ritter are in full view.

An examination of these districts, the character and quantity of their ores, and the facilities for working them, convinces one that they need only a moderate amount of capital, and better means of transportation, to develop them to a condition that will pay well and permanently.

Fresno county, July 26th.

TERRIBLE storm on the Atlantic coast,

NORTH FORK AND MINARET MINING DISTRICTS, FRESNO COUNTY.

than ten feet, yet an assay in San Francisco, for proposed buyers, from mixed specimens of this surface ore, gave \$145.32 silver per ton.

The following claims have been located in

The North Fork District,

Running from northwest to southeast. In the central ledge, Advance, Sentinel, Atlanta (also called Cosmopolite by counter claimants), Silver Queen, Center, No Name, Blue Grass. Next ledge east, Nevada (1,500 feet or more farther northwest than the Advance), Merced, Echo, Blue Bird, Surprise, Eureka, Kate Claxton, Fresno, El Capitan. Your readers will understand that all these claims embrace the usual 1,500 feet in length and 600 in width. Eastward there is space for two sets of claims, but little prospected as yet. Then east of this space, and immediately under the basaltic cliffs of Summit ridge, such as bound the upper edges of many ridges here, are five other claims on a ledge parallel to those above mentioned. The most northerly is the Keystone. Then comes the unclaimed space for three ledges. Then, in succession, the Record, Mountain View, Mexican and Tiptop. West of the central vein comes, first, the Eclipse claim, 1,500 feet farther north than the Advance, and its extensions, the Lakeview, Hudson, Julia, Homestake, Alice, Monitor. Farther west, beginning on a line with the Julia, comes the Amazon with its southeast

reaches the city limits. El Capitan, the most southern extension of Nevada or Fresno ledge, is just north of Highland City. A mile or more south of this town site is California Lion ledge extending to Rice lake, also the Liberator and other ledges. Other prospecting and locations are going on northwest of this belt up to the very sources of the Joaquin, which are but four or five miles in direct line northwest of this district. The accompanying map indicates the various locations with general accuracy, though no regular surveys have yet been made.

Work on Shafts and Tunnels

Has progressed farther here than in the Minaret district, and results are highly encouraging.

The following shafts have been sunk: On Atlanta, 10 feet; Silver Queen, 14 feet; DeSoto, 10 feet. But most work has been done on the Eureka and Surprise. On both these, tunneling has begun, in addition to shafts sunk deep enough to prove the fine quality of the surface ore. A tunnel is commenced on the Eureka, 125 feet below the out-croppings, to reach the ledges in 260 feet. The altitude of its mouth is about 10,000 feet. They hope to finish it by October next.

In the Surprise, owned by J. T. Dodds and E. B. Lovelace—discoverer of the Enterprise mine near Fresno Flats—a tunnel in hard black slate, six feet high by four wide was finished 140

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.

INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machine and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price \$3 each, or \$30 per dozen. Sent post-paid to any address upon receipt of price.

SETH MARSHALL, Jr., Agent,

309 California Street, San Francisco, Cal.

Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

THE ELKINS

"BOSS" GOLD AMALGAMATOR.

Is the Best, Simplest and Cheapest Amalgamator in Use.

Nothing about it to get out of order or wear out. Weighs only 500 lbs—heaviest piece weighs 160 lbs. Is automatic in its working. Measures, feeds, screens and passes all material through a large body of quicksilver; then washes and cleans without care or attention. Requires no more power than a large grindstone. Uses water over and over again where water is scarce. All water required can pass through a 1-inch pipe. Capacity, two to four tons per hour. Saves 90% of precious metals. Price, \$250. Pump \$25 extra. Send for circular.

FOR CHECKS, DRAFTS, ETC.

A sure protection against the raising of Checks and Drafts. Merchants should have their Checks and Drafts printed on this paper for self-protection.

H. S. CROCKER & CO.

Agents for the Pacific Coast.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Ingersoll Rock Drills.

In use in the largest and best
Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Ad-
justed than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

MINERS' HORSE-POWER.

This Power is especially adapted to working mines, blasting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

Winchester Repeating Rifle,

MODEL 1873.

One-third size by Dr. E. H. Pardee.

The Strength of All its Parts,

The Simplicity of its Construction,

The Rapidity of its Fire,

The Power and Accuracy of its Discharge,

The Impossibility of Accident in Loading,

String measuring from center of target to center of each shot, 32 inches. Average distance of each shot, 1 9-100 inches.

Commend it to the attention of all who use a Rifle, either for Hunting, Defense, or Target Shooting.

The San Francisco Agency is now fully supplied with all the various kinds and styles of Arms manufactured by the Winchester Repeating Arms Company, to wit:

Round barrels, plain and set, 24 inch—blued. Octagon barrel, plain, 24 inch—blued. Octagon barrel, set, 24, 28, 30 inch—blued. Octagon barrel, set extra heavy, 24, 28, 30 inch—blued. Octagon barrel, set, 24, 28, 30—extra finished, case hardened and check stocks. Octagon barrel, set extra heavy, 24, 28, 30 inch—extra finished—C. H. & C. S. Octagon barrel, set, 24, 28, 30 inch—beautifully finished—O. H. & O. S., known as "One of One Thousand." Octagon barrel, set, gold, silver and nickel plated and engraved. Carabines blued, also gold, silver and nickel plated. Military rifle muskets, model 1873. Rifles, muskets and carbines, model 1866. RELOADING TOOLS, PRIMERS AND PARTS OF ARMS.

A heavy stock of Cartridges Manufactured by the W. R. A. Co., for all kinds of Rifles and Pistols, constantly on hand and warranted the best in the market.

Sole Agent for Dupont's Mining, Blasting, Cannon, and Celebrated Brands of Sporting Powder.

JOHN SKINKER, No. 115 Pine Street, San Francisco,

SOLE AGENT FOR THE PACIFIC COAST.

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

STEEL CASTINGS.

From 1-4 to 10,000 lbs. Weight.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc. 12,000 Crank Shafts of this Steel now running proved superior to wrought iron. CRANK SHAFTS, CROSSHEADS and GEARING, specialties. Circulars and Price Lists free. Address

Chester Steel Castings Co.

Works, Chester, Pennsylvania. 407 Library St., Philadelphia

Machinery.

GOLD AND SILVER Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular. We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 39 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

[CONTINUED FROM PAGE 117.]

per ton. The ores at the end of the drift are now assaying \$700.

COLORADO.

ITEMS.—Denver *Tribune*, Aug. 13: The Bonanza tunnel in San Juan is in now over 700 ft, and will probably cut the large vein very soon at a depth of 650 ft below the surface. A new lead has lately been discovered at the Cerrillos, assaying, at a depth of 4 ft, 425 ounces. The carbonate belt on Eagle river has been found to be nine miles long on the north side of the river and six miles on the south. The heaviest body yet found is 13 ft thick, but as yet no deep holes have been sunk. At Rosita a few days ago Mr. Yeoman relocated an abandoned claim on Robinson hill, quite near town, and discovered a fine, but small, vein of mineral, which, at only three ft in depth, assayed 57 ounces in silver per ton. He calls it the Cow Boy. The Queen Victoria claim, owned by Messrs. Bassick, Smith, Davis and Steiger, on the north slope of Bassick hill, has a shaft of 100 ft deep. They have but very little mineral at the bottom of the shaft. Chellew & Co., lessees of the Kent County, have struck a feeder to the main vein, coming in from the southwest, on the hanging wall, in the intermediate or middle vein being struck below the 500 level. The crevice of smelting iron is quite wide and is very rich. The Red Cloud mine at Ouray has its shaft down 50 ft, showing a two-ft pay streak. At Silver Cliff, a few days ago A. Marietta, who has been digging a hole in the Carbonate district north of the Baltic lode, and not far from the Rambler, struck a very good body of ore at the depth of 52 ft, which showed up by actual mill run 27 ounces of silver per ton. The North Star mine on King Solomon mountain is turning out more and richer ore than ever before. Already over 500 sacks of ore have been shipped to Lake City. A lot of 28 sacks taken from the third and lower level on the mine mill run at Lake City 64 ounces in silver to the ton. There are now en route to Lake over 80 sacks of this same class of ore. There are over 20 tons now on the dump, and the shipments have already amounted to 40 tons which have averaged over 250 ounces to the ton. The Clinton mine at Leadville has developed a 12-ft vein of ore. A sample of 400 pounds was brought to this city which gave a return of 110 ounces. Another lot from the same county, weight 80 pounds, was shown to contain 57 ounces of lead.

ITEMS.—Silver Cliff *Prospector*, Aug. 11: On one vein among the hills east of Silver Cliff, and north of Rosita, there are five mines—the Polonia, Twenty-six, Tecumseh, Ben Franklin and Dirigo. The first named of these is located on a hill about midway between the town of Rosita and Bassick's mine. The others, in the order named, follow the course of the vein, which, from the Polonia, bears west 20 degrees north. The Ben Franklin, owned by Messrs. W. Thurman and others, is one of the oldest mines in the district, and has four shafts, No. 2 of which is not used. No. 1 is connected by drift with No. 3, the present working shaft, now down 210 ft, and No. 4, to which a drift is being run at a depth of 50 ft. The pay streak of the Ben Franklin averages about eight inches in width, its component parts consisting of galena, gray copper, zinc and pyrites of iron. The average of mill runs had by present owners is said to be 123 ounces silver, its assay value at present depth being about 16 ounces. The average width of the ore body proper approximates eight inches, its component parts being gray copper, galena, zinc, granulated iron and pyrites, its average value about 120 ounces, the range being from 40 up to 310 ounces per ton.

PERUVIAN.—Georgetown *Courier*, Aug. 14: This property is located in Peru district, near the head of Snake river. The vein is immense, being from two to four ft thick of solid galena, and, as the location is probably in the same belt as the Stevens mine, they can look for a grade that will average about the same as that mine. The property is opened by three shafts, and a crosscut tunnel has been driven 215 ft but has not yet intersected the lode.

IDAHO.

ITEMS.—World, Aug. 12: At Atlanta the Buffalo mine is looking better at present than it has for the last two years. They are taking out from seven to eight tons of ore per day. The rock is worth about \$150 per ton. The Monarch mine is not looking very well now, but they expect to make a strike south here. The new shaft will be completed to the surface in about two weeks. The Last Chance made a run of about 200 tons, which paid well. Mr. J. N. Pedlar is working his mine, the Taloma, and is taking out some good ore. He made a run of 75 tons this spring. About 50 tons of ore from Hawley & Co.'s mine, on Shaw's mountain, crushed in Plowman's mill, yielded about \$40 per ton.

YANKEE FORK.—World, Aug. 15: A depth of 50 ft has been attained on the Montana mine, which is steadily improving in width and richness with depth. The ore body is from six to eight ft wide and very rich.

MONTANA.

ITEMS.—Butte *Miner*, Aug. 12: The station chamber on the 500 level of the Alice is in 33 ft from the shaft and is being driven ahead. The station, which is being driven directly towards the ledge will be 13 ft longer than its present length. From its face a smaller tunnel will be run to tap the lode. Upon completion of the station the work of advancing towards the lode will be arrested until the pump will have been set up and tested, when the task of cutting through the water-tight footwall casing will be undertaken. The lode is estimated to be between 100 and 110 ft from the shaft on the 500 level, but owing to the decreasing hardness of the rock as the footwall is approached the work of driving to it will be much more than half done when the northern face of the station is reached. The Grove Gulch mill was shut down the other day, to remain closed indefinitely, and the hands paid off. This mill has been employed upon ore from the Olive Branch, which, although very rich, has become too base for reduction by the crushing process. A lot of Olive Branch ore sampled lately is reported as averaging 400 ounces per ton, but very base, so base that it must be smelted.

OREGON.

VIRTUE MINE.—Baker City *Democrat*, Aug. 13: Work has been commenced at the Virtue mine. The pumps are at work drawing the water from the shafts, and as soon as this is accomplished a full set of hands will be put into the mine and ore taken out to keep the mill constantly running.

UTAH.

THOMPSON & McNALLY MINE.—Silver Reef *Miner*, Aug. 13: This property is situated on the White Reef and bounded on the north by the Leeds company's claim known as the Maynard, on the south by the McKelvey, and on the east by the Stormont. The tunnel is in 150 ft. The width of ore measures six ft between the hanging wall, three ft of which is impregnated with horn silver and black sulphurets, and assays from \$200 to \$1,500 per ton in silver, some going even as high as \$8,000 per ton. There is exposed in the drift on the south side, where the tunnel will penetrate the west side of the reef, a body of ore for a distance of 280 ft, ready to take out as soon as the tunnel is through. There are also about 500 tons piled on the different dumps, which will average between \$30 and \$35 per ton.

NOVEL USE OF ETHER.—A prisoner, named Uhlmann, recently barricaded himself in his cell at Vevey, Switzerland, and defied the gendarmes to take him before the judges. It was not thought advisable to shoot him, and the court would not wait till he was starved into surrender, so ether was thrown into the cell until he became sufficiently stupefied to be harmless.

An Infamous Business.

May the curse of God rest upon an impious traffic which is robbing our State of its manhood; turning the feet of our sons away from the paths of industry, and transforming our sober and industrious fathers into condemned criminals. It certainly would seem that enough of disgraces and destruction has already been visited upon our homes to warn all those who have anything of self-esteem and family love remaining, to shun an indulgence which saps their strength, distracts their minds, casts to the winds the fruits of a life-time's labors, and leads them to deeds which bend their heads with shame and plunge their families into the depths of despair. But the end is not yet. Infatuation still leads men to pursue gain, even where loss and ruin are sure to be found, and the community, while it pours out its sympathy for the fallen, still accords respectability to a traffic which should be held in the deepest detestation for the evil which it brings upon society.

Instances recur which are so like hundreds which have gone before that the details need hardly be recited. A man, with a beautiful home, a devoted wife and a group of lovely children; a man who, by nearly 20 years of constant devotion to the interests of his employers, had won their fullest confidence, and who stood before the community as a model of unyielding industry, suddenly appears a confessed criminal, and in a day is transformed from an apparent promoter of public virtue to an enemy of society, who has his liberty only at the price of pledges from his friends. Does anyone need to be told the cause of the transformation? Is it necessary to tell again how this glittering snare of the stock gambler entrapped the feet which trod so firmly the path of virtue and industry; how the mind was turned from its sober thoughts and honorable ambitions by the visions of short-cuts to fortunes; how the blinding promises were false as perdition, and yet so alluring that he who pursued them was led in the deeper, until the funds of employers, confidently entrusted to his care, were secretly appropriated to feed the unholy fire of the gambling passion; how this theft was ere long discovered, and how the bars closed in the wreck of reputation and of honor, while tears flow in this home and heart-felt sympathy and regret fill a neighborhood.

But what use is it to recite such painful incidents when this evil seems to grow the while? No sooner does some wretched conspiracy of impious men fall into the hands of the police than another, even more glaring, springs into view. And this people—poor, senseless throng—crowd the counters of the swindling cormorants giving their hard-earned savings in return for naught but worthless promises. For a few days the gold pours in, and then the throng comes some morning to find the doors closed and their treasures gone beyond recovery. One would think that these specious frauds would be recognized by the shallowest brain, and yet experience proves that victims are always ready to jostle one another in the rush to ruin. It is plain that there should be some power to guard the people against these coarser forms of fraud, for these are the traps that catch the poor and the unwary. There is one thing that the public should demand from the press, and that is, that the insidious snares should not be spared in the public prints. What use is it that the editorial columns of our dailies warn people against them so long as their glittering advertisements are received by the publishers? What use to preach virtue when the hands are filled with the rewards from vice? The press is a sharer in the fortunes made by ruining homes and wrecking lives, and so long as this is true, the friends of humanity will have cause to mourn.

The public has its eye open to the evil, and yet it lives. In the city, some business houses which employ many men have their spies abroad and as soon as any man in their employ takes a hand in stocks, he is watched and his accounts scrutinized daily. What better evidence could he had of the way in which the business is regarded by our leading men? And yet the evil grows. Not satisfied with the gambling in railway and other securities at the East, they have introduced the California system, and already victims are falling just as men fall when plague settles down upon a city. Only last week it was a bank officer who went down to perdition in New York, by breach of trust, through gambling in stocks. Thus, east and west, the evil spreads, and distrust rises as virtue sinks. What can aave the people? Nothing, unless each one works to save himself, and to spread a truer idea of the danger. Let it be understood that whoever enters the business in any form places his foot upon dangerous ground, which may ere long part and engulf him. As a man values his reputation; as he loves his home, his wife, his children; as he values a right life here and cherishes a hope beyond, let him shun the evil—the crowning evil of the day.—*Pacific Rural Press.*

The Bishop of Belgium excommunicates all teachers in schools established by the State under the education law.

It is estimated that the log crop of Wisconsin this year will reach 1,635,000,000 feet, against 1,075,000,000 last year.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY.]

FOR THE WEEK ENDING AUGUST 12TH, 1879.

218,420—BED CLOTHING—O. S. Baker, S. F.
218,472—OVERALLS—P. Banner, S. F.
218,489—MUFFLE FURNACE—James R. Clark, S. F.
218,514—STEAM PUMP—John Gates, Portland, Ogn.
218,446—FEED-WATER HEATER AND CONDENSER FOR STEAM BOILERS—R. Llewellyn, S. F.
7,584—SARSAPARILLA OR BLOOD PURIFIER—Trademark—Geo. L. Carroll, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

OVERALLS.—Pincus Banner, S. F. Dated Aug. 12th. This invention relates to certain improvements in overalls; and it consists of a peculiar re-enforce for the seat, which is formed with three extensions or projections, two of which extend down the inside leg-seams, while the third extends over the middle seam up to the front opening of the pants. The corner of the pocket openings are prevented from being torn out by a peculiar system of cross-stitching, so that all supplemental re-enforcing pieces at these points may be dispensed with.

MUFFLE FURNACE.—James R. Clark, S. F. Dated Aug. 12th. The invention consists in providing a series of muffles communicating with each other, the fire passing between the hearth of one and the arch of the other on its way to the stack, so that although this ore is roasted it is nowhere in the presence of the flames; it further consists in connecting with the furnaces a series of tubs or vats for holding ore, into which chlorine, generated in the furnace while the ore is roasting, is led. These tubs or vats are provided with pumps for circulating the liquor and passing it through and through the ore as fresh chlorine is continuously added from the furnaces.

Machinery at the Mechanics' Fair.

While examining the different exhibits spread out in this most attractive manner at the pavilion, there are certain ones which attract differently disposed people. The ponderous, noisy mining machinery, and the rattling of the agricultural implements, possesses a charm for many, while others prefer the quest of the more innocent looking exhibits. The machinery is all placed on the right of the pavilion as you come in through the Mission-street entrance. Here are found the iron-lathe machines, engines, pumps, ore-crushers, amalgamators, blowers, type-foundry, threshers, reapers and mowers, corn shellers, and every variety of curious and heavy machinery, in full operation. In the midst stands the large Corliss engine, which furnishes power for the whole, and the Brush electro-dynamic generator, which assists in throwing light upon the subject. The displays of saws of every variety and form, and for every use, and the bright brass foundry work, are to the minds of many as beautiful an exhibit as is that of fine arts in the gallery. Many visitors watch the moving machinery as if fascinated. The smaller and more modest displays are pleasant to look at, but the almost human intelligence exhibited in the workings of heavy and unwieldy metal is more satisfying to the imagination. The results of machinery, as seen in the iron and steel manufactures worked into shape as if of some plastic material, produces a feeling of content, and every visitor, long after the visit, retains a general impression of the various details, and convince him that he has learned something about the capacities of this coast.

The Continental Oil Company.

The Continental Oil Company of this city (F. B. Taylor & Co.), importers of and dealers in illuminating and lubricating oils, have extensive warehouses on Fifth, Berry, and Channel streets, where their oil is received in their own patent compartment cars, and from this point is distributed in bulk or packed in their oil-canning establishment. Messrs. Taylor & Co., being agents for the leading manufacturers in their line at the East, have unequalled facilities, and receiving their goods direct, profits to middle men are avoided. The oils imported by rail are necessarily fresh, being direct from the refiners. They keep on hand the Eureka, Alladin, Luster, Golden Star, Downer's, Taylor's, Excelsior, Continental Water White, and other high test oils. They deal also in naphtha, benzine, gasoline, crude petroleum, kerosene fluid, white lead,

turpentine, Sapolio, axle grease, Cologne spirits, alcohol, etc., all of the best brands in market. A full assortment of paints, paint oils, colors, zincs, varnishes, crack colors, brushes, etc., etc., is kept. The offices and store are at 120 and 122 Front street. Messrs. F. B. Taylor & Co. have been in the business for many years, and are well known as keeping a very large stock at reasonable prices.

News in Brief.

CHOLERA is still prevalent at Cahul. GEORGIA Mormons are emigrating to Utah. PIANOS are being shipped from New York to Japan.

SCHUYLER COLFAX is to reappear as a lecturer during the coming season.

THE loss by the Tremont Temple fire in Boston will not exceed \$105,000.

THE Porte has appointed Plenipotentiaries to arrange the Greek frontier.

THE firman of investiture of Tewfik Pasha was received at Cairo, August 18th.

SPECIE in the Imperial Bank of Germany decreased 539,000 marks the past week.

THE drouth in Cashmere continues, and this condition of the people is deplorable.

TWO streams of lava flowed from Mt. Vesuvius recently as far as the base of the cone.

A RIOT occurred at Quebec August 18th, in which a great number of persons were injured.

NELLIE GRANT SARTORIS is not dead, but Mrs. E. Sartoris (formerly Adelaide Kimball) is.

THE imports of specie at New York last week amounted to \$1,073,416—\$963,587 being in gold.

THE Cashier of the Citizens' National Bank at Washington is a defaulter in the sum of \$60,000.

MEMBERS of the British Parliament are about to visit America to take cognizance of the present harvest.

BULLION withdrawn from the Bank of England August 18th, £30,000, which was shipped to Canada.

ANOTHER death from yellow fever occurred August 18th at the New York quarantine hospital.

THE Napoleonic fete of the 15th of August was omitted in Paris this year, the first time in 30 years.

COLLECTOR BALL has been elected Mayor of Sitka, a civil government having been fully organized.

MISSISSIPPI planters fear a great increase in the exodus of laborers after the cotton crop is gathered.

PARIS has 65,000 houses, London 460,000 more than Paris, Berlin and New York combined.

A MAN was arrested near Erie, Pa., the other day charged with a murder committed in Philadelphia in 1865.

HUNGARY produces more horses than any other country of its size—2,158,000 for a population of 15,000,000.

IN Illinois this year 42,041,252 bushels of wheat will be harvested—the largest crop ever raised in that State.

IT is stated at Madrid that the marriage of King Alfonso and Archduchess Maria will take place at the end of October.

A GENTLEMAN, representing 250 Scots, has gone into the Yellowstone country to find an American home for them.

RYE, the principal bread material of Germany, will only yield half a crop this year, while wheat will yield a full harvest.

AT Liverpool August 18th wheat was quoted at 8s 6d to 9s 6d for average California white, and 9s 5d to 9s 10d for chub.

A PRIVATE gentleman at Moscow, Russia, has been sentenced to 12 years in the mines for attacking and insulting a sentinel.

THE great map of the moon upon which Dr. Julius Schmidt, of Athens, has been at work since 1867, shows 32,856 craters and ring-like formations on the lunar surface; and 348 rills and clefts. The number of craters would be increased to 100,000, according to Schmidt's estimate, in a complete chart representing the moon as it appeared when seen with a magnifying power of six hundred.

Fine Arts at the State Fair

The citizens of Sacramento are arranging to have an art exhibition during the coming State fair at that place. A large sum of money will be expended in its formation, and the gentlemen who compose the committee are a sufficient guarantee that business is meant. W. H. Mills, B. D. Kennedy, S. C. Densen, H. H. Pierson, George H. Redding and Norton Bush, form the executive committee, with Wm. P. Coleman of the State Board of Agriculture. A new art gallery connected with the pavilion at Sacramento will be erected, and no means left untried to make a success. The C. P. R. R. will forward all articles for exhibition free of charge.

Communications should be addressed to I. N. Hoag, Secretary of State Agricultural Society, Sacramento, and will receive prompt attention. The State fair opens on the 8th of September, and closes on the 13th, so that applications for space should be made at once.

We learn from the *Record-Union* that the art gallery being constructed on the balcony on the west side of the pavilion is almost completed. There will be 160 feet of wall space added to the space heretofore devoted to the display of pictures. Mr. Norton Bush, who has charge of the business on behalf of the committee, visited San Francisco and received positive assurances from Bradford, Perry, Brooks, Tavernier, Keith, Rix, Deakin, Tojetti, Strauss, Denny, Hahn, Williams and others that they will exhibit. Thomas Hill was out of the city, but arrangements will be made to have some of his work on exhibition. Of these, Bradford, Brooks, Tavernier, Keith, Rix, Tojetti, Strauss, and Williams never before exhibited at the fair. The exhibition of the coming State fair will far surpass any of its predecessors. The very best works of the artists named will be on exhibition.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWLEY—California.
A. C. KNOX—Pacific Coast.
S. V. BLANCHER—State of Nevada.
G. W. McGRAW—Santa Clara County.
MILTON KENNEDY—Kern and Inyo counties.
J. B. BACHSLER—Shasta County, Cal.
H. H. MESSINGER—Arizona.

Back Numbers Wanted.

The following volumes and single copies of the MINING AND SCIENTIFIC PRESS are wanted at this office, for which a reasonable price is offered:

Year.	Volume.	2 Complete volumes, 1st half (of year).
1870	20	2 Complete volumes, 1st half (of year).
1871	21	2 Complete volumes, 1st half (of year).
1872	22	2 Complete volumes, 1st half (of year).
1873	23	2 Complete volumes, 1st half (of year).
1874	24	2 Complete volumes, 1st half (of year).
1875	25	2 Complete volumes, 1st half (of year).
1876	26	2 Complete volumes, 1st half (of year).
1877	27	2 Complete volumes, 1st half (of year).
1878	28	2 Complete volumes, 1st half (of year).
1879	29	2 Complete volumes, 1st half (of year).
